The University of Texas at Austin
Financial Mathematics

An interdisciplinary field on the crossroads of stochastic processes, stochastic analysis, optimization, partial differential equations, finance, financial economics, decision analysis, statistics and econometrics.

It studies derivative securities and investments, and the management of financial risks.

Started in the 1970s with the pricing of derivative securities.
Derivative securities

Derivatives are financial contracts offering payoffs written on underlying (primary) assets.

Their role is to eliminate, reduce or mitigate risk.
Major breakthrough

Black-Scholes-Merton 1973

- The price of a derivative is the value of a portfolio that reproduces the derivative’s payoff
- The components of this replicating portfolio yield the hedging strategies

This idea together with Itô’s stochastic calculus started the field of Financial Mathematics

Louis Bachelier (1870-1946)

Bachelier model (1900)

$W_t$ a standard Brownian motion and $\mu, \sigma$ constants
increment evolves as

$$S_{t+\delta} - S_t = \mu \delta + \sigma (W_{t+\delta} - W_t)$$

Bachelier’s work was neglected for decades
It was not recognized until Paul Samuelson introduced it to Economics
Samuelson model (1965)

log-normal stock prices

\[ dS_s = \mu S_s ds + \sigma S_s dW_s \]

widely used in finance practice

European call

\[ C_t \quad (S_T - K)^+ \]

0 \quad t \quad T

initiation \quad exercise
Replication (Black-Scholes-Merton)

• Market: stock $S$ and a bond $B$ ($dB_s = rB_s ds$)

• Find a pair of stochastic processes $(\alpha_s, \beta_s)$, $t \leq s \leq T$, such that a.s. at $T$,

$$\alpha_T S_T + \beta_T B_T = (S_T - K)^+$$

• The derivative price process $C_s$, $t \leq s \leq T$, is then given by

$$C_s = \alpha_s S_s + \beta_s B_s$$

• Price at initiation: $C_t = \alpha_t S_t + \beta_t B_t$

• Hedging strategies: $(\alpha_s, \beta_s)$, $t \leq s \leq T$
• **Replication** using self-financing strategies

\[ C_s = C_t + \int_t^s \alpha_u dS_u + \int_t^s \beta_u dB_u \]

• Postulate a price representation \( C_s = h(S_s, s) \) for a smooth function \( h(x, t) \)

• Itô’s calculus

\[ C_s = h(S_t, t) \]

\[ + \int_t^s \left( h_t(S_u, u) + \mu S_u h_x(S_u, u) + \frac{1}{2} \sigma^2 S_u^2 h_{xx}(S_u, u) \right) du \]

\[ + \int_t^s \sigma S_u h_x(S_u, u) dW_u \]
Black and Scholes pde

The function $h(x, t)$ solves

$$rh = h_t + \frac{1}{2} \sigma^2 x^2 h_{xx} + rxh_x$$

with $h(0, t) = 0$ and $h(x, T) = (x - K)^+$

European call price process

$$C_s = h(S_s, s)$$

Hedging strategies

$$(\alpha_s, \beta_s) = \left( h_x(S_s, s), \frac{h(S_s, s) - h_x(S_s, s) S_s}{B_s} \right)$$
A universal pricing theory
for general price processes (semimartingales)
Arbitrage-free pricing of derivative securities
Harrison, Kreps, Pliska (1979,1981)

Arbitrage

A market admits arbitrage in \([t, T]\) if the outcome \(X_T\) of self-financing strategies satisfies \(X_t = 0\), and

\[
P(X_T \geq 0) = 1 \quad \text{and} \quad P(X_T > 0) > 0
\]

In arbitrage-free markets, derivative prices are given by

\[
C_t = E_Q \left( \frac{B_T}{B_t} C_T \middle| F_t \right)
\]

\(\mathbb{Q} \sim \mathbb{P}\) under which (discounted) assets are martingales

Model-independent pricing theory

\[
\mathbb{P} \rightarrow \mathbb{Q} \rightarrow E_Q (\cdot \mid F_t)
\]

Linear pricing rule and change of measure
Mathematics and derivative securities

- Martingale theory and stochastic integration
  Derivative prices are martingales under $\mathbb{Q}$
  Hedging strategies are the integrands (martingale representation)

- Malliavin calculus for sensitivities ("greeks")

- Markovian models - (multi-dim) linear partial differential equations
  Early exercise claims - optimal stopping, free-boundary problems
  Exotics - linear pde with singular boundary conditions

- Credit derivatives - copulas, jump processes

- Bond pricing, interest rate derivatives, yield curve: linear stochastic PDE
Some problems of current interest

• Stochastic volatility
• Correlation, causality
• Systemic risk
• Counterparty risk
• Liquidity risk, funding risk
• Commodities and Energy
• Calibration
• Market data analysis
The other side of Finance: Investments
Derivative securities and investments

While in derivatives the aim is to eliminate the risk, the goal in investments is to profit from it

- Derivatives industry uses highly quantitative methods
- Academic research and finance practice have been working together, especially in the 80s and 90s
- Traditional investment industry is not yet very quantitative
- A unified "optimal investment" theory does not exist to date
- Ad hoc methods are predominantly used

Disconnection between academic research and investment practice

drawdown, leverage
Academic research in investments
Modeling investor’s behavior
Utility theory

- Created by Daniel Bernoulli (1738) responding to his cousin, Nicholas Bernoulli (1713) who proposed the famous St. Petersburg paradox, a game of “unreasonable” infinite value based on expected returns of outcomes.

- D. Bernoulli suggested that utility or satisfaction has diminishing marginal returns, alluding to the utility being concave (see, also, Gabriel Cramer (1728)).

- Oskar Morgenstern and John von Neumann (1944) published the highly influential work “Theory of games and economic behavior”. The major conceptual result is that the behavior of a rational agent coincides with the behavior of an agent who values uncertain payoffs using expected utility.
Utility function and its marginal

\[ U(x) \]

\[ U'(x) \]

Inada conditions:
\[ \lim_{x \to 0} U'(x) = \infty \quad \text{and} \quad \lim_{x \to \infty} U'(x) = 0 \]

Asymptotic elasticity:
\[ \lim_{x \to \infty} \frac{xU'(x)}{U(x)} < 1 \]
Stochastic optimization
and optimal portfolio construction
Merton’s portfolio selection continuous-time model

- start at $t \geq 0$ with endowment $x$
  - market $(\Omega, \mathcal{F}, (\mathcal{F}_t), \mathbb{P})$, price processes

- follow investment strategies, $\pi_s \in \mathcal{F}_s$, $t < s \leq T$

- map their outcome $X^{\pi}_T \rightarrow E_\mathbb{P} \left( U \left( X^{\pi}_T \right) | \mathcal{F}_t, X^{\pi}_t = x \right)$

- maximize terminal expected utility (value function)

$$V(x, t) = \sup_{\pi} E_\mathbb{P} \left( U \left( X^{\pi}_T \right) | \mathcal{F}_t, X^{\pi}_t = x \right)$$

Stochastic optimization approaches

Markovian models
- Dynamic Programming Principle
  Bellman (1950)

Non-Markovian models
- Duality approach
  Bismut (1973)
Markovian models

Stock price: \( dS_t = S_t \mu (Y_t, t) \, dt + S_t \sigma (Y_t, t) \, dW_t \)

Stochastic factors: \( dY_t = b (Y_t, t) \, dt + a (Y_t, t) \, d\tilde{W}_t; \) correlation \( \rho \)

Controlled diffusion (wealth): \( dX^\pi_s = \pi_s \mu (Y_t, t) \, dt + \pi_s \sigma (Y_s, s) \, dW_s, \, X_t = x \)

**Dynamic Programming Principle (DPP)**

\[
V (X^\pi_s, Y_s, s) = \sup_{\pi} E^P \left( V (X^\pi_{s'}, Y_{s'}, s') \mid \mathcal{F}_s \right)
\]

**Hamilton-Jacobi-Bellman equation**

\[
V_t + \max_{\pi \in \mathbb{R}} \left\{ \frac{1}{2} \pi^2 \sigma^2 (y, t) \, V_{xx} + \pi (\mu (y, t) \, V_x + \sigma (y, t) \, a (y, t) \, V_{xy}) \right\}
+ \frac{1}{2} a^2 (y, t) \, V_{yy} + b (y, t) \, V_y = 0,
\]

with \( V (x, y, T) = U (x) \)
Optimal portfolios (feedback controls)

\[ \pi^* (x, y, t) = -\frac{\mu (y, t)}{\sigma^2 (y, t)} \frac{V_x}{V_{xx}} - \rho \frac{a (y, t)}{\sigma (y, t)} \frac{V_{xy}}{V_{yy}} \]

\[ \pi_s^* = \pi^* (X_s^*, Y_s, s) \text{ and } dX_s^* = \pi_s^* \mu (Y_t, t) \, dt + \pi_s^* \sigma (Y_s, s) \, dW_s \]

**Difficulties**

- set of controls non-compact, state-constraints
- degeneracies, lack of smoothness, validity of verification theorem
- value function as viscosity solution of HJB, smooth cases for special examples

- existence, smoothness and monotonicity properties of \( \pi^* (x, y, t) \)
- probabilistic properties of optimal processes \( \pi_s^*, X_s^* \) and their ratio

Karatzas, Shreve, Touzi, Bouchard, Pham, Z.,...
Duality approach in optimal portfolio construction
Dual optimization problem - utility convex conjugate

\[ \tilde{U}(y) = \max_{x > 0} \left( U(x) - xy \right) \]

- Introduced in stochastic optimization by Bismut (1973)
- Introduced in optimal portfolio construction by Bismut (1975) and Foldes (1978)
- Further results by Karatzas et al (1987) and Cox and Huang (1989)
- Xu (1990) shows that the HJB linearizes for complete markets
- Kramkov and Schachermayer (1999) establish general results for semimartingale models
Semimartingale stock price models

$\mathcal{H}$: predictable processes integrable wrt the semimartingale $S$

$\mathcal{X}(x) = \left\{ X : X_t = x + \int_0^t H_s \cdot dS_s, \ t \in [0, T], \ H \in \mathcal{H} \right\}$

$\mathcal{Y} = \left\{ Y \geq 0, \ Y_0 = 1, \ XY \text{ semimartingale for all } X \in \mathcal{X} \right\}$

$\mathcal{Y}(y) = y\mathcal{Y}, \ y > 0$

Asymptotic elasticity condition: $\limsup_{x \to \infty} \left( \frac{xU'(x)}{U(x)} \right) < 1$

Primal problem

$$u(x) = \sup_{X \in \mathcal{X}(x)} E^p \left( U(X_T) \right)$$

Dual problem

$$\tilde{u}(y) = \inf_{Y \in \mathcal{Y}(y)} E^p \left( \tilde{U}(Y_T) \right)$$
If $u(x) < \infty$, for some $x$, and $\tilde{u}(y) < \infty$ for all $y > 0$, then:

- $\tilde{u}(y) = \sup_{x>0} (u(x) - xy)$
- $\tilde{u}(y) = \inf_{Q \in \mathcal{M}^e(S)} E_P \left( \tilde{U} \left( y \frac{dQ}{dP} \right) \right)$, $y > 0$, with $\mathcal{M}^e(S)$ the set of martingale measures $Q \sim P$
- if $Q^*$ optimal, the terminal optimal wealth (primal problem) $X_T^{x,*}$ is given by
  \[ U'(X_T^{x,*}) = u'(x) \frac{dQ^*}{dP} \]

Kramkov and Schachermayer, Karatzas, Cvitanic, Zitkovic, Sirbu, ...
Some extensions
Coupled stochastic optimization problems

Systems of HJB equations

Delegated portfolio management

investor $\xrightarrow{\text{fees, capital}}$ manager

manager $\xrightarrow{\text{risk, return}}$ investor

\[
V^i (x, t) = \sup_{A^i} E_{\mathbb{P}} \left( U^i \left( X_T, I^m_{t\leq s \leq T} \right) \middle| \mathcal{F}_t, X_t = x \right)
\]

\[
V^m (y, t) = \sup_{A^m} E_{\mathbb{P}} \left( U^m \left( Y_T, I^i_{t\leq s \leq T} \right) \middle| \mathcal{G}_t, Y_t = y \right)
\]

$I^m$ and $I^i$: inputs from the manager (performance, risk taken) and the investor (investment targets)

Benchmarking and asset specialization among competing fund managers

\[
V^1 (x, t) = \sup_{A^1} E_{\mathbb{P}_1} \left( U_1 \left( X_T, Y^*_T \right) \middle| \mathcal{F}_t, X_t = x \right)
\]

\[
V^2 (y, t) = \sup_{A^2} E_{\mathbb{P}_2} \left( U_2 \left( Y_T, X^*_T \right) \middle| \mathcal{G}_t, Y_t = y \right)
\]
Proportional transaction costs

- $N$ stocks, one riskless bond
- Pay proportionally $\alpha^i$ for selling and $\beta^i$ for buying the $i^{th}$ stock
  \[ X_s : \text{bond holding}, \quad Y_s = \left( Y^1_s, \ldots, Y^N_s \right) : \text{stock holdings}, \quad t \leq s \leq T, \]
  \[
dX_s = rX_s ds + \sum_{i=1}^{N} \alpha^i dM^i_s - \sum_{i=1}^{N} \beta^i dL^i_s
  \]
  \[
dY^i_s = \mu^i Y^i_s ds + \sigma^i Y^i_s dW^i_s + dL^i_s - dM^i_s
  \]

Variational inequalities with gradient constraints

\[
\min \left( - V_t - \mathcal{L}^{(y_1, \ldots, y_N)} V - rxV_x, -a^1 V_x + V_{y_1}, \beta^1 V_x - V_{y_1}, \right.
\]
\[
\vdots
\]
\[
- a^N V_x + V_{y_N}, \beta^N V_x - V_{y_N} \right) = 0,
\]

with \( V(x, y_1, \ldots, y_N, T) = U \left( x + \sum_{i=1}^{N} \alpha^i y_i 1_{\{y_i \geq 0\}} + \sum_{i=1}^{N} \beta^i y_i 1_{\{y_i \leq 0\}} \right) \)
Liquidation of financial positions and price impact

**big investor**: delegates liquidation to "major agent"

**major agent**: liquidates in the presence of many small agents
small agents: **noise traders** and **high-frequency traders**

**Optimal liquidation is an interplay between speed and volume**

Too fast $\rightarrow$ price impact
Too slow $\rightarrow$ unfavorable price fluctuations

**Mean-field games**

- Aggregate impact from noise traders
- Aggregate impact from high-frequency traders
Model uncertainty and optimal portfolio construction
Knightian uncertainty (model ambiguity)
Frank Knight (1921)

The historical measure $\mathbb{P}$ might not be a priori known

- Gilboa and Schmeidler (1989) built an axiomatic approach for preferences towards both risk and model ambiguity. They proposed the robust utility form

  $$X_T^\pi \to \inf_{Q \in \mathcal{Q}} E_Q (U (X_T^\pi)),$$

  where $U$ is a classical utility function and $\mathcal{Q}$ a family of subjective probability measures

Standard criticism: the above criterion allows for very limited, if at all, differentiation of models with respect to their plausibility
Maccheroni, Marinacci and Rustichini (2006) extended the above approach to

\[ X_T^\pi \to \inf_{Q \in \mathcal{Q}} \left( E_Q \left( U \left( X_T^\pi \right) \right) + \gamma \left( Q \right) \right) \]

where the functional \( \gamma \left( Q \right) \) serves as a *penalization* weight to each \( Q \)-market model.

**Entropic penalty and entropic robust utility**

\[ \gamma \left( Q \right) = H \left( Q \mid \mathbb{P} \right) \quad \text{with} \quad H \left( Q \mid \mathbb{P} \right) = \int \frac{dQ}{d\mathbb{P}} \ln \left( \frac{dQ}{d\mathbb{P}} \right) d\mathbb{P} \]

\[ \inf_{Q \in \mathcal{Q}} \left( E_Q \left( U \left( X_T^\pi \right) \right) + \gamma \left( Q \right) \right) = \ln E_{\mathbb{P}} \left( e^{-U(X_T)} \right) \]

Hansen, Talay, Schied, Föllmer, Frittelli, Weber …
Maxmin stochastic optimization problem

Stock dynamics: $S_t = \left( S^1_t, \ldots, S^d_t \right)$, $t \in [0, T]$, semimartingales

Wealth dynamics: $X^\alpha_t = x + \int_0^t \alpha_s \cdot dS_s$, $X^\alpha_t \geq 0$, $t \geq 0$

Objective:

$$v(x) = \sup_{X \in \mathcal{X}(x)} \inf_{Q \in \mathcal{Q}} \left( E_Q \left( U \left( X_T \right) \right) + \gamma(Q) \right),$$

where $\mathcal{Q} = \{ Q \ll \mathbb{P} | \gamma(Q) < \infty \}$

Duality approach

$$u(y) = \inf_{Y \in \mathcal{Y}_Q(y)} \inf_{Q \in \mathcal{Q}} \left( E_Q \left( \tilde{U} \left( Y_T \right) \right) + \gamma(Q) \right),$$

where $\tilde{U}(y) = \sup_{x > 0} \left( U(x) - xy \right)$
Investment practice
Portfolio selection criteria

Single-period criteria

- **Mean-variance** $\leftrightarrow$ maximize the mean return for fixed variance
- **Black-Litterman** $\leftrightarrow$ allows for subjective views of the investor

Long-term criterion

- **Kelly criterion** $\leftrightarrow$ maximize the long-term growth

While using these criteria allows for tractable solutions, they have major deficiencies and limitations which do not capture important features like the evolution of both the market and the investor’s targets.
Mean–variance optimization
Harry Markowitz (1952)

Performance of portfolio returns $\leftrightarrow$ mean, variance

- Single period: $0, T$
- Allocation weights at $t = 0$: $a = (a^1, \cdots, a^n); \sum_{i=1}^{n} a^i = 1$
- Asset returns: $R_T = (R^1_T, \cdots, R^n_T)$
- Return on allocation: $R^a_T = \sum_{i=1}^{n} a^i R^i_T$

**Mean–variance optimization**

For a fixed acceptable variance $v$ maximize the mean,

$$\max_{a: \sum_i a_i = 1 \atop \text{Var}(R^a_T) \leq v} \mathbb{E}_p(R^a_T)$$

or

For a fixed desired mean $m$ minimize the variance,

$$\min_{a: \sum_i a_i = 1 \atop \mathbb{E}_p(R^a_T) \geq m} \text{Var}(R^a_T)$$
Efficient frontier

![Graph showing the efficient frontier with axes labeled \( \mu^a \) and \( \sigma^a \).]
Despite its popularity and wide use, MV has major deficiencies!

- Model error and unstable solutions
- Time–inconsistency of optimal portfolios
- Dynamic extensions not available to date
Model error and unstable solutions

• Quality and availability of market data not always good
• Estimation error very high
• Optimal allocation highly sensitive to this error
• Historical returns frequently used, not “forward–looking”
• Optimal portfolios are frequently “extreme”, unnatural, high short–selling
• Asset managers are familiar with only certain asset classes and sectors (“familiarity versus diversification” issue)

Some of these issues can be partially addressed by the Black–Litterman criterion which adjusts the equilibrium asset returns by the manager’s individual views on “familiar” assets (classes or sectors)
Time–inconsistency of MV problem

At time $t = 0$

\[ v_{0 \rightarrow 2T} \]

\[ a_{0}^{*,0} \]

\[ 0 \]

\[ a_{T}^{*,0} \]

\[ T \]

\[ 2T \]

At time $t = T$

\[ v_{T \rightarrow 2T} = v_{0 \rightarrow 2T} \]

\[ a_{T}^{*,T} \neq a_{T}^{*,0} \]

\[ 0 \]

\[ T \]

\[ 2T \]

Game theoretic approach (Björk et al. (2014))
Dynamic (rolling investment times) MV optimization

\[ v_0 \rightarrow T, \quad v_T \rightarrow 2T, \quad v_{2T} \rightarrow 3T, \quad \ldots \]

- This problem is **not** the same as setting, at \( t = 0 \), the “three–period” variance target \( v_0 \rightarrow 3T \).
- Is there a **discrete process** \( v_0 \rightarrow 2T, \ v_T \rightarrow 2T, \ \ldots, \ v_{nT} \rightarrow (n+1)T, \ \ldots \) modelling the targeted conditional variance (from one period to the next) that will generate time–consistent portfolios?
- What is the **continuous–time limit** of this construction?
- Can it be addressed by mapping the MV problem to the time–consistent expected utility problem? **No!** because the expected utility approach produces a solution “backwards in time”!
Can the theoretically foundational approach of expected utility meet the investment practice?

**Similar limitations and discrepancies arise between expected utility, and the Black-Litterman and Kelly criteria.** Practical features of these industry criteria do not fit in the expected utility framework, which however has major deficiencies.
Such issues and considerations prompted the development of the forward investment performance approach (Musiela and Z., 2002- ).
Market environment

- \((\Omega, \mathcal{F}, (\mathcal{F}_t), \mathbb{P})\); \(W = (W^1, \ldots, W^d)\)

- Traded securities

\[
\begin{aligned}
\left\{ 
    dS^i_t &= S^i_t\left(\mu^i_t dt + \sigma^i_t \cdot dW_t \right), & S^i_0 > 0, & 1 \leq i \leq k \\
    dB_t &= r_t B_t dt, & B_0 = 1
\end{aligned}
\]

\(\mu_t, r_t \in \mathbb{R}, \sigma^i_t \in \mathbb{R}^d\) bounded and \(\mathcal{F}_t\)-measurable stochastic processes

- Wealth process \(dX^\pi_t = \sigma_t \pi_t \cdot (\lambda_t dt + dW_t)\)

- Postulate existence of an \(\mathcal{F}_t\)-measurable stochastic process \(\lambda_t \in \mathbb{R}^d\) satisfying

\[
\mu_t - r_t 1 = \sigma^T_t \lambda_t
\]

- No assumptions on market completeness
Forward investment performance process

optimality across trading times

\[ U(x, t) \in \mathcal{F}_t \]

\[ U(x, s) \in \mathcal{F}_s \quad U(x, t) \in \mathcal{F}_t \]

\[ U(x, s) = \sup_{A} E_{\mathbb{P}}(U(X_{t}^{\pi}, t)|\mathcal{F}_s, X_{s}^{\pi} = x) \]

• Does such a process always exist?
• Is it unique?
• Axiomatic construction?
• How does it relate to criteria in investment practice?
Forward investment performance process

\[ U(x, t) \text{ is an } \mathcal{F}_t\text{-adapted process, } t \geq 0 \]

- The mapping \( x \rightarrow U(x, t) \) is strictly increasing and strictly concave
- For each self-financing strategy \( \pi \) and the associated (discounted) wealth \( X_t^\pi \)
  \[ E_{\mathbb{P}}(U(X_t^\pi, t) \mid \mathcal{F}_s) \leq U(X_s^\pi, s), \quad 0 \leq s \leq t \]
- There exists a self-financing strategy \( \pi^* \) and associated (discounted) wealth \( X_t^{\pi^*} \) such that
  \[ E_{\mathbb{P}}(U(X_t^{\pi^*}, t) \mid \mathcal{F}_s) = U(X_s^{\pi^*}, s), \quad 0 \leq s \leq t \]
The forward performance SPDE
Let $U(x, t)$ be an $\mathcal{F}_t$—measurable process such that the mapping $x \to U(x, t)$ is strictly increasing and concave. Let also $U(x, t)$ be the solution of the stochastic partial differential equation

$$dU(x, t) = \frac{1}{2} \frac{|\sigma \sigma^+ \mathcal{A}(U(x, t) \lambda + a)|^2}{\mathcal{A}^2 U(x, t)} \, dt + a(x, t) \cdot dW_t$$

where $a = a(x, t)$ is an $\mathcal{F}_t$—adapted process, and $\mathcal{A} = \frac{\partial}{\partial x}$. Then $U(x, t)$ is a forward performance process.

Once the volatility is chosen the drift is fully specified if we know $(\sigma, \lambda)$.
The volatility of the investment performance process

This is the novel element in the new approach

- The volatility models how the current shape of the performance process is going to diffuse in the next trading period
- The volatility is up to the investor to choose, in contrast to the classical approach in which it is uniquely determined via the backward construction of the value function process
- In general, \( a(x, t) = F(x, t, U, U_x, U_{xx}) \) may depend on \( t, x, U \), its spatial derivatives etc.
- When the volatility is not state-dependent, we are in the zero volatility case

Specifying the appropriate class of volatility processes is a central problem in the forward performance approach

Musiela and Z., Nadtochiy and Z., Nadtochyi and Tehranchi, Berrier et al., El Karoui and M’rad
The zero volatility case: \( a(x, t) \equiv 0 \)
Time-monotone performance process

The forward performance SPDE simplifies to

\[ dU(x, t) = \frac{1}{2} \frac{\sigma^+ A(U(x, t)\lambda)^2}{A^2 U(x, t)} \, dt \]

The process

\[ U(x, t) = u(x, A_t) \quad \text{with} \quad A_t = \int_0^t |\lambda_s|^2 \, ds \]

and \( u(x, t) \) a strictly increasing and concave w.r.t. \( x \) function solving

\[ u_t = \frac{1}{2} \frac{u_x^2}{u_{xx}} \]

is a solution

MZ (2006, 2009)
Berrier, Rogers and Tehranchi (2009)
Optimal wealth and portfolio processes and a fast diffusion equation
Local risk tolerance function and a fast diffusion equation

\[ r_t + \frac{1}{2} r^2 r_{xx} = 0 \]

\[ r(x, t) = -\frac{u_x(x, t)}{u_{xx}(x, t)} \]

System of SDEs at the optimum

\[ R_t^* \triangleq r(X_t^*, A_t) \quad \text{and} \quad A_t = \int_0^t |\lambda_s|^2 ds \]

Then

\[
\begin{cases}
  dX_t^* = R_t^* \lambda_t \cdot (\lambda_t dt + dW_t) \\
  dR_t^* = r_x(X_t^*, A_t) dX_t^*
\end{cases}
\]

and the optimal portfolio is \( \pi_t^* = R_t^* \sigma_t^+ \lambda_t \).
Complete construction

utility inputs, heat eqn and fast diffusion eqn

\[ u_t = \frac{1}{2} \frac{u_x^2}{u_{xx}} \quad \leftrightarrow \quad h_t + \frac{1}{2} h_{xx} = 0 \quad \leftrightarrow \quad r_t + \frac{1}{2} r^2 r_{xx} = 0 \]

positive solutions to heat eqn and Widder’s thm

\[ h_x(x, t) = \int_{\mathbb{R}} e^{xy - \frac{1}{2} y^2 t} \nu(dy) \]

optimal wealth process

\[ X_t^{*, x} = h\left( h^{(-1)}(x, 0) + A_t + M_t, A_t \right) \quad M = \int_0^t \lambda_s \cdot dW_s, \quad \langle M \rangle_t = A_t \]

optimal portfolio process

\[ \pi_t^{*, x} = r(X_t^{*, A_t}) \sigma_t^+ \lambda_t = h_x\left( h^{(-1)}(X_t^{*, A_t}), A_t \right) \sigma_t^+ \lambda_t \]
Forward performance approach under Knightian uncertainty
Forward robust portfolio criterion
(Kallbald, Oblovak, Z.)

- allow flexibility with respect to the investment horizon
- incorporate "learning"
- produce optimal investment strategies closer to the ones used in practice

Forward robust criterion

A pair \((U(x, t), \gamma_{t,T}(Q))\) of a utility process and a penalty criterion which satisfies, for all \(0 \leq t \leq T\),

\[
U(x, t) = \text{ess sup}_{\alpha} \text{ess inf}_{Q \in Q_{t,T}} \left( E_Q \left( U(x + \int_t^T \alpha_s \cdot dS_s, T) \bigg| \mathcal{F}_t \right) + \gamma_{t,T}(Q) \right)
\]

with \(Q_T = \{ Q \in Q : Q|_{\mathcal{F}_T} \sim P|_{\mathcal{F}_T} \}\)

This criterion gives rise to an ill-posed SPDE corresponding to a zero-sum stochastic differential game
Connection with the Kelly criterion
Is there a pair \((U(x, t), \gamma_{t,T})\) that yields the Kelly optimal-growth portfolio?

“True” model
\[ dS_t = S_t \left( \lambda_t dt + \sigma_t dW^1_t \right), \quad (W^1, W^2) \text{ under } \mathbb{P} \]

“Proxy” model:
\[ dS_t = S_t \left( \hat{\lambda}_t dt + \sigma_t d\hat{W}^1_t \right), \quad (W^1, W^2) \text{ under } \hat{\mathbb{P}} \]

For each \(Q \sim \hat{\mathbb{P}}\) and each \(T > 0\), let \(\eta_t = (\eta^1_t, \eta^2_t), 0 \leq t \leq T,\)

\[
\frac{dQ}{d\hat{\mathbb{P}}} \bigg|_{\mathcal{F}_T} = \mathcal{E} \left( \int_0^T \eta^1_s d\hat{W}^1_s + \int_0^T \eta^2_s d\hat{W}^2_s \right)_T
\]

Doléans-Dade exponential:
\[
\mathcal{E}(Y)_t = \exp \left( Y_t - \frac{1}{2} \langle Y \rangle_t \right)
\]

Candidate penalty functionals
\[
\gamma_{t,T}(Q) = \mathbb{E}_Q \left( \int_t^T g(\eta_s, s) ds \bigg| \mathcal{F}_t \right)
\]
Logarithmic risk preferences
and quadratic penalty

\[ U(x, t) = \ln x - \frac{1}{2} \int_0^t \frac{\delta_s}{1 + \delta_s} \hat{\lambda}_s^2 d\hat{s}, \quad t \geq 0, \; x > 0 \]

\[ \gamma_{t,T}(Q^n) = \mathbb{E}_{Q^n} \left( \left( \int_t^T \frac{\delta_s}{2} |\eta_s|^2 d\eta_s \right) | \mathcal{F}_t \right) \]

- The process \( \delta_t \) is adapted, non–negative and controls the strength of the penalization
- It models the confidence of the investor re the "true" model
(Fractional) Kelly strategies and forward optimal controls

Investor chooses proxy model ($\hat{\lambda}_t$) and confidence level ($\delta_t$)

Optimal measure $Q^{\eta^*}$

$$\eta^*_t = \left( -\frac{\hat{\lambda}_t}{(1 + \delta_t)}, 0 \right)$$ and $$\frac{dQ^{\eta^*}}{d\hat{P}} = \mathcal{E} \left( -\int_0^\cdot \frac{\hat{\lambda}_t}{1 + \delta_t} d\hat{W}_t^1 \right)$$

Optimal forward Kelly portfolio

$$\bar{\pi}_t = \frac{\delta_t}{1 + \delta_t} \frac{\hat{\lambda}_t}{\sigma_t}$$

- If $\delta_t \uparrow \infty$ (infinite trust in the estimation), then $\bar{\pi}_t \downarrow \frac{\hat{\lambda}_t}{\sigma_t}$, which is the Kelly strategy associated with the most likely model $\hat{P}$
- If $\delta_t \downarrow 0$ (no trust in the estimation), then $\bar{\pi}_t \downarrow 0$ and the optimal behavior is to invest nothing in the stock
## Open problems

### Academic research

- Study of forward SPDE
- Existence and uniqueness for concave, increasing slns
- Characterize admissible volatility processes
- Approx. of slns via finite-dim Markovian multi-factor processes
- Ergodic properties of portfolios and wealth processes

### Investment practice

- Reconcile with MV forward, dynamic construction
- Reconcile with Black-Litterman inject manager’s views in the forward volatility and drift
- Reconcile with Kelly criterion model ambiguity and fractional Kelly
- Provide a normative platform to connect these three criteria

### Forward performance approach
