#### Research support by:

Problem addressed: The talk concerns numerical methods for boundary value problems of the form

(BVP) 
$$\begin{cases} Au(\boldsymbol{x}) = g(\boldsymbol{x}), & \boldsymbol{x} \in \Omega, \\ Bu(\boldsymbol{x}) = f(\boldsymbol{x}), & \boldsymbol{x} \in \Gamma, \end{cases}$$

where  $\Omega$  is a domain with boundary  $\Gamma$ , and where A is a linear elliptic differential operator (with possibly variable coefficients).

Examples of problems we are interested in:

- The equations of linear elasticity.
- Stokes' equation.
- Helmholtz' equation (at least at low and intermediate frequencies).
- Time-harmonic Maxwell (at least at low and intermediate frequencies).

Archetypical example: Poisson equation with Dirichlet boundary data:

$$egin{cases} -\Delta u(oldsymbol{x}) = g(oldsymbol{x}), & oldsymbol{x} \in \Omega, \ u(oldsymbol{x}) = f(oldsymbol{x}), & oldsymbol{x} \in \Gamma. \end{cases}$$

Problem addressed: The talk concerns numerical methods for boundary value problems of the form

(BVP) 
$$\begin{cases} Au(\boldsymbol{x}) = g(\boldsymbol{x}), & \boldsymbol{x} \in \Omega, \\ Bu(\boldsymbol{x}) = f(\boldsymbol{x}), & \boldsymbol{x} \in \Gamma, \end{cases}$$

where  $\Omega$  is a domain with boundary  $\Gamma$ , and where A is a linear elliptic differential operator (with possibly variable coefficients).

Linear solution operators: As a warmup, let us consider the Poisson equation

$$-\Delta u(\mathbf{x}) = g(\mathbf{x}) \qquad \mathbf{x} \in \mathbb{R}^2$$

(with suitable decay conditions at infinity to ensure uniqueness). The solution is given by

(SLN) 
$$u(\mathbf{x}) = \int_{\mathbb{R}^2} \phi(\mathbf{x} - \mathbf{y}) g(\mathbf{y}) d\mathbf{y}, \qquad \mathbf{x} \in \mathbb{R}^2.$$

where the "fundamental solution" of the Laplace operator  $-\Delta$  on  $\mathbb{R}^2$  is defined by

$$\phi(\boldsymbol{x}) = -\frac{1}{2\pi} \log |\boldsymbol{x}|.$$

In principle very simple. Numerically non-trivial, however: The operator is *global*, so discretizing it leads to a *dense* matrix. (There is also the singular kernel to worry about!)

Problem addressed: The talk concerns numerical methods for boundary value problems of the form

(BVP) 
$$\begin{cases} Au(\boldsymbol{x}) = g(\boldsymbol{x}), & \boldsymbol{x} \in \Omega, \\ Bu(\boldsymbol{x}) = f(\boldsymbol{x}), & \boldsymbol{x} \in \Gamma, \end{cases}$$

where  $\Omega$  is a domain with boundary  $\Gamma$ , and where A is a linear elliptic differential operator (with possibly variable coefficients).

Linear solution operators: A general solution operator for (BVP) takes the form

(SLN) 
$$u(\mathbf{x}) = \int_{\Omega} G(\mathbf{x}, \mathbf{y}) g(\mathbf{y}) d\mathbf{y} + \int_{\Gamma} F(\mathbf{x}, \mathbf{y}) f(\mathbf{y}) dS(\mathbf{y}), \qquad \mathbf{x} \in \Omega,$$

where G and F are two kernel functions that depend on A, B, and  $\Omega$ .

**Bad:** The kernels G and F in (SLN) are generally *unknown*.

(Other than in trivial cases — constant coefficients and very simple domains.)

Bad: The operators in (SLN) are global.

Dense matrices upon discretization.  $O(N^2)$  cost?  $O(N^3)$  cost?

Good: The operators in (SLN) are friendly and nice.

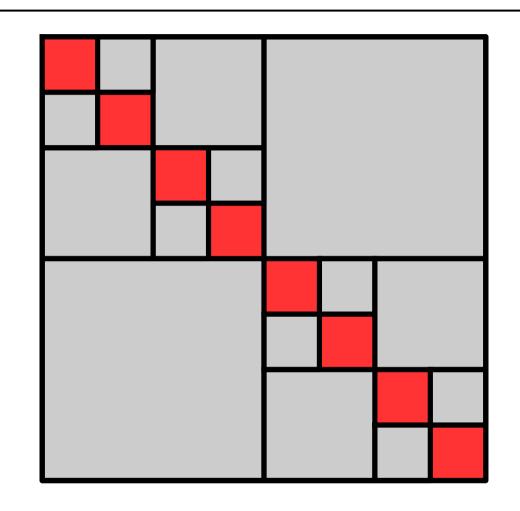

Bounded, smoothing, often fairly stable, etc.

Recall that we are interested in solving the PDE 
$$\begin{cases} Au(\mathbf{x}) = g(\mathbf{x}), & \mathbf{x} \in \Omega, \\ Bu(\mathbf{x}) = f(\mathbf{x}), & \mathbf{x} \in \Gamma. \end{cases}$$
 (BVP) Explicit solution formula:  $u(\mathbf{x}) = \int_{\Omega} G(\mathbf{x}, \mathbf{y}) g(\mathbf{y}) d\mathbf{y} + \int_{\Gamma} F(\mathbf{x}, \mathbf{y}) f(\mathbf{y}) dS(\mathbf{y}), & \mathbf{x} \in \Omega. \end{cases}$  (SLN)

Explicit solution formula: 
$$u(\mathbf{x}) = \int_{\Omega} G(\mathbf{x}, \mathbf{y}) g(\mathbf{y}) d\mathbf{y} + \int_{\Gamma} F(\mathbf{x}, \mathbf{y}) f(\mathbf{y}) dS(\mathbf{y}), \qquad \mathbf{x} \in \Omega.$$
 (SLN)

Recurring idea: Upon discretization, (SLN) leads to a matrix with off-diagonal blocks of low numerical rank.

This property can be exploited to attain linear or close to linear complexity for operations such as matrix-vector multiply, matrix-matrix multiply, LU factorization, matrix inversion, forming of Schur complements, etc.

All gray blocks have low rank.

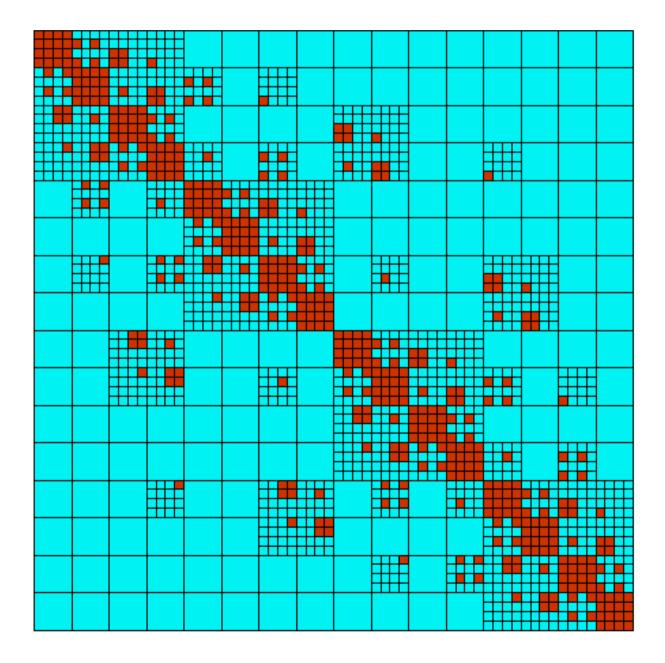

Strong connections to Calderón-Zygmund theory for singular integral operators.

Recall that we are interested in solving the PDE 
$$\begin{cases} Au(\boldsymbol{x}) = g(\boldsymbol{x}), & \boldsymbol{x} \in \Omega, \\ Bu(\boldsymbol{x}) = f(\boldsymbol{x}), & \boldsymbol{x} \in \Gamma. \end{cases}$$
 (BVP) Explicit solution formula:  $u(\boldsymbol{x}) = \int_{\Omega} G(\boldsymbol{x}, \boldsymbol{y}) g(\boldsymbol{y}) d\boldsymbol{y} + \int_{\Gamma} F(\boldsymbol{x}, \boldsymbol{y}) f(\boldsymbol{y}) dS(\boldsymbol{y}), & \boldsymbol{x} \in \Omega. \end{cases}$  (SLN)

Explicit solution formula: 
$$u(\mathbf{x}) = \int_{\Omega} G(\mathbf{x}, \mathbf{y}) g(\mathbf{y}) d\mathbf{y} + \int_{\Gamma} F(\mathbf{x}, \mathbf{y}) f(\mathbf{y}) dS(\mathbf{y}), \qquad \mathbf{x} \in \Omega.$$
 (SLN)

In real life, tessellation patterns of rank structured matrices tend to be more complex ...

Recall that we are interested in solving the PDE 
$$\begin{cases} Au(\mathbf{x}) = g(\mathbf{x}), & \mathbf{x} \in \Omega, \\ Bu(\mathbf{x}) = f(\mathbf{x}), & \mathbf{x} \in \Gamma. \end{cases}$$
 (BVP) Explicit solution formula:  $u(\mathbf{x}) = \int_{\Omega} G(\mathbf{x}, \mathbf{y}) g(\mathbf{y}) d\mathbf{y} + \int_{\Gamma} F(\mathbf{x}, \mathbf{y}) f(\mathbf{y}) dS(\mathbf{y}), & \mathbf{x} \in \Omega. \end{cases}$  (SLN)

The talk will describe recent work on algorithms that numerically construct an approximation to (SLN).

When using these algorithms, the process of solving (BVP) splits into two stages:

- 1. "Factorization" or "build" stage: Build a representation of the inverse operator.
- 2. "Solve" stage: Apply the computed inverse to given data f and g.

Typical characteristics of methods of this type:

- Memory usage tends to be high.
- Stage 1 tends to be slower than an iterative solve, when convergence is fast.
- Stage 2 is almost always VERY fast.

#### FDS is most competitive when:

- Getting iterative methods to converge rapidly is hard.
- When the cost of Stage 1 can be amortized over many solves.

# **History:**

1980s: Rokhlin and Greengard develop the Fast Multipole Method.

1991: Beylkin, Coifman, Rokhlin: Fast algorithms exist for most solution operators.

1996: Michielssen, Boag, Chew: Fast direct solvers for 3D scattering problems in certain geometries.

1998 onwards: Hackbusch, Bebendorf, Börm, Grasedyck, Khoromskij, Sauter, Tyrtyshnikov, ... develop  $\mathcal{H}$  and  $\mathcal{H}^2$ -frameworks that provide explicit recipes for operator algebra in  $O(n \log^r n)$  operations for r moderate.

#### **Outline of talk:**

- Introduction: Problem formulation & solution operators. [Done!]
- Curse of dimensionality.
- Interaction ranks why are they small? How small are they?
- Versions of fast direct solvers "strong" versus "weak" etc.
- High order discretizations and fast direct solvers.

# **Curse of dimensionality**

Algorithms involving rank-structured matrices scale *very* poorly with dimension. For instance, for the classical Fast Multipole Method, key quantities scale as:

Dimension	Typical ranks	Number of "neighbors"	Length of "interaction list"
1	2	2	3
2	10–50	8	27
3	50–500	26	189
d	$(\log(1/\varepsilon))^{d-1}$	3 <sup>d</sup> – 1	$6^{d} - 3^{d}$

#### **Curse of dimensionality**

Algorithms involving rank-structured matrices scale very poorly with dimension.

For instance, for the classical Fast Multipole Method, key quantities scale as:

Dimension	Typical ranks	Number of "neighbors"	Length of "interaction list"
1	2	2	3
2	10–50	8	27
3	50–500	26	189
d	$(\log(1/\varepsilon))^{d-1}$	3 <sup>d</sup> – 1	$6^d - 3^d$

For fast direct solvers, the scaling with dimension is equally problematic:

	Dimension	Current state of affairs
1		Extremely fast. Linear scaling is easy to attain.
2		Quite fast in practice, but simple methods do not scale linearly.
3		Slow. Basic methods cannot go much beyond $N \approx 10^7$ .

#### **Curse of dimensionality**

Algorithms involving rank-structured matrices scale *very* poorly with dimension.

For instance, for the classical Fast Multipole Method, key quantities scale as:

Dimension	Typical ranks	Number of "neighbors"	Length of "interaction list"
1	2	2	3
2	10–50	8	27
3	50–500	26	189
d	$(\log(1/\varepsilon))^{d-1}$	3 <sup>d</sup> – 1	$6^d - 3^d$

For fast direct solvers, the scaling with dimension is equally problematic:

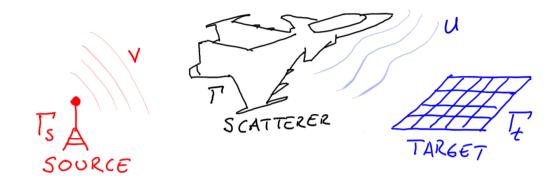

<b>Effective</b> Dimension	Current state of affairs
1	Extremely fast. Linear scaling is easy to attain.
2	Quite fast in practice, but simple methods do not scale linearly.
3	Slow. Basic methods cannot go much beyond $N \approx 10^7$ .

Fortunately, we can often reduce the *effective* dimensionality.

For many 3D problems, the dense problems we need to invert "live" on 2D domains!

# Curse of dimensionality: Dimension reduction via an integral equation

Recall that many boundary value problems can advantageously be recast as *boundary integral equations*. Consider, e.g., (sound-soft) acoustic scattering from a finite body:

(3) 
$$\begin{cases} -\Delta u(\mathbf{x}) - \kappa^2 u(\mathbf{x}) = 0 & \mathbf{x} \in \mathbb{R}^3 \setminus \overline{\Omega} \\ u(\mathbf{x}) = v(\mathbf{x}) & \mathbf{x} \in \partial \Omega \\ |\mathbf{x}| \to \infty & |\mathbf{x}| \left( \partial_{|\mathbf{x}|} u(\mathbf{x}) - i\kappa u(\mathbf{x}) \right) = 0. \end{cases}$$

The BVP (3) is in many ways equivalent to the BIE

$$(4) -\pi i\sigma(\mathbf{x}) + \int_{\partial\Omega} \left( \left( \partial_{\mathbf{n}(\mathbf{y})} + i\kappa \right) \frac{e^{i\kappa|\mathbf{x} - \mathbf{y}|}}{|\mathbf{x} - \mathbf{y}|} \right) \sigma(\mathbf{y}) \, dS(\mathbf{y}) = f(\mathbf{x}), \mathbf{x} \in \partial\Omega.$$

The integral equation (4) has several advantages over the PDE (3), including:

- The domain of computation  $\partial\Omega$  is finite.
- The domain of computation  $\partial\Omega$  is 2D, while  $\mathbb{R}^3\backslash\overline{\Omega}$  is 3D.
- Equation (4) is inherently well-conditioned (as a "2<sup>nd</sup> kind Fredholm equation").

A serious drawback of integral equations is that they lead to *dense coefficient matrices*. Since we are interested in constructing inverses anyway, this is unproblematic for us!

# **Curse of dimensionality: Dimension reduction via sparse direct solvers**

Let us next consider what happens if we directly discretize the PDE (using, say, finite elements or finite differences) to obtain a linear system

$$Au = b$$

involving a *sparse* coefficient matrix **A**.

**Key idea:** Do a sparse LU factorization based on a "nested dissection" ordering of the grid as an outer solver. Then use rank structured matrix algebra to deal with the dense matrices that arise.

# **Curse of dimensionality: Dimension reduction via sparse direct solvers**

**A 2D model problem:** Let  $\Omega = [0, 1]^2$  and  $\Gamma = \partial \Omega$ . We seek to solve

(5) 
$$\begin{cases} -\Delta u(\boldsymbol{x}) = g(\boldsymbol{x}), & \boldsymbol{x} \in \Omega, \\ u(\boldsymbol{x}) = f(\boldsymbol{x}), & \boldsymbol{x} \in \Gamma. \end{cases}$$

We introduce an  $n \times n$  grid on  $\Omega$  with nodes  $\{x_j\}_{j=1}^N$  where  $N = n^2$ , see Figure A. Letting  $\mathbf{u} = [\mathbf{u}(j)]_{j=1}^N$  denote a vector of approximate solution values,  $\mathbf{u}(j) \approx u(x_j)$ , and using the standard five-point stencil to discretize  $-\Delta$ , we end up with a sparse linear system

$$Au = b$$

where  $[Au](k) = \frac{1}{h^2} (4 u(k) - u(k_s) - u(k_e) - u(k_n) - u(k_w))$ , see Figure B.

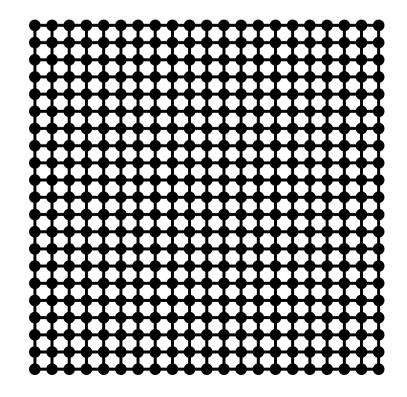

Figure A: The grid

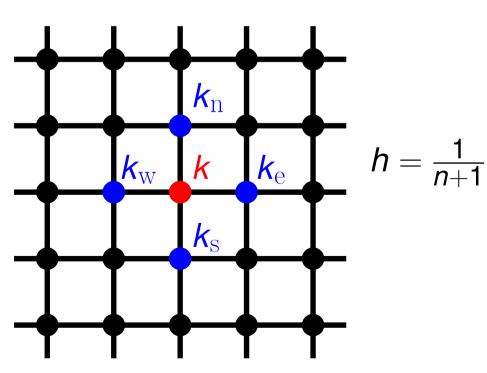

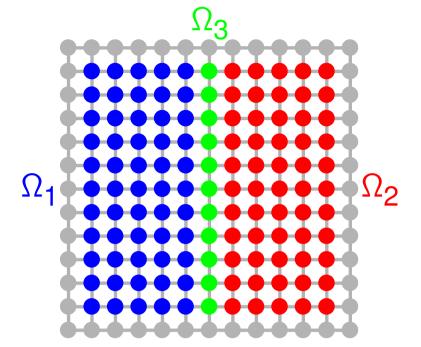

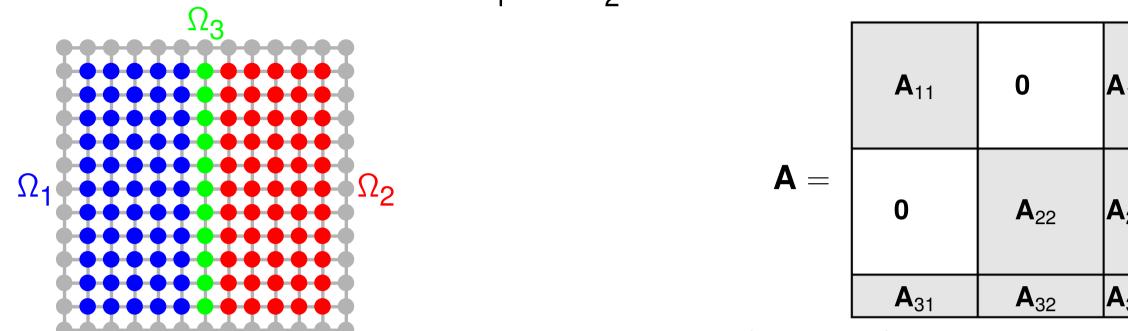

Figure B: The 5-point stencil

**Divide-and-conquer:** Split the nodes in three groups as shown so that there are no connections between nodes in  $\Omega_1$  and  $\Omega_2$ . Then **A** has zero blocks as shown:

	<b>A</b> <sub>11</sub>	0	<b>A</b> 13
$\mathbf{A} =$	0	<b>A</b> <sub>22</sub>	<b>A</b> <sub>23</sub>
	<b>A</b> <sub>31</sub>	<b>A</b> <sub>32</sub>	<b>A</b> <sub>33</sub>

**Divide-and-conquer:** Split the nodes in three groups as shown so that there are no connections between nodes in  $\Omega_1$  and  $\Omega_2$ . Then **A** has zero blocks as shown:

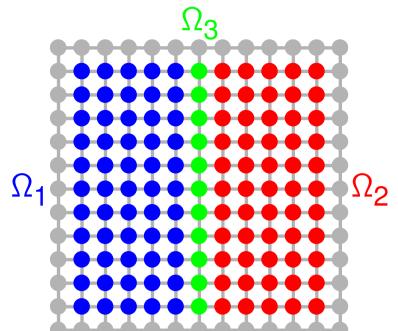

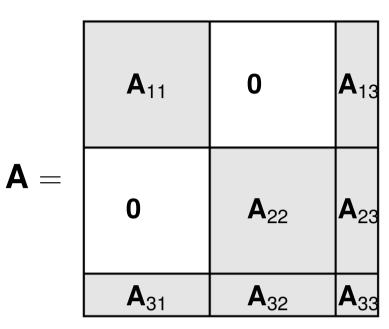

Now suppose that we can somehow construct  $\mathbf{A}_{11}^{-1}$  and  $\mathbf{A}_{22}^{-1}$ . Then

$$\mathbf{A} = \begin{bmatrix} \mathbf{I} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{I} & \mathbf{0} \\ \mathbf{A}_{31} \mathbf{A}_{11}^{-1} & \mathbf{A}_{32} \mathbf{A}_{22}^{-1} & \mathbf{I} \end{bmatrix} \begin{bmatrix} \mathbf{A}_{11} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{A}_{22} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{S}_{33} \end{bmatrix} \begin{bmatrix} \mathbf{I} & \mathbf{0} & \mathbf{A}_{11}^{-1} \mathbf{A}_{13} \\ \mathbf{0} & \mathbf{I} & \mathbf{A}_{22}^{-1} \mathbf{A}_{23} \\ \mathbf{0} & \mathbf{0} & \mathbf{I} \end{bmatrix}$$

where  $S_{33} = A_{33} - A_{31}A_{11}^{-1}A_{13} - A_{32}A_{22}^{-1}A_{23}$  is a *Schur complement*.

Divide-and-conquer: Split the nodes in three groups as shown so that there are no connections between nodes in  $\Omega_1$  and  $\Omega_2$ . Then **A** has zero blocks as shown:

Now suppose that we can somehow construct  $A_{11}^{-1}$  and  $A_{22}^{-1}$ . Then

$$\mathbf{A} = \begin{bmatrix} \mathbf{I} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{I} & \mathbf{0} \\ \mathbf{A}_{31} \mathbf{A}_{11}^{-1} & \mathbf{A}_{32} \mathbf{A}_{22}^{-1} & \mathbf{I} \end{bmatrix} \begin{bmatrix} \mathbf{A}_{11} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{A}_{22} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{S}_{33} \end{bmatrix} \begin{bmatrix} \mathbf{I} & \mathbf{0} & \mathbf{A}_{11}^{-1} \mathbf{A}_{13} \\ \mathbf{0} & \mathbf{I} & \mathbf{A}_{22}^{-1} \mathbf{A}_{23} \\ \mathbf{0} & \mathbf{0} & \mathbf{I} \end{bmatrix}$$

$$\begin{array}{|c|c|c|c|c|} \hline A_{11} & 0 & 0 \\ \hline 0 & A_{22} & 0 \\ \hline 0 & 0 & S_{33} \\ \hline \end{array}$$

$$\begin{bmatrix} \mathbf{I} & \mathbf{0} & \mathbf{A}_{11}^{-1} \mathbf{A}_{13} \\ \mathbf{0} & \mathbf{I} & \mathbf{A}_{22}^{-1} \mathbf{A}_{23} \\ \mathbf{0} & \mathbf{0} & \mathbf{I} \end{bmatrix}$$

where  $S_{33} = A_{33} - A_{31}A_{11}^{-1}A_{13} - A_{32}A_{22}^{-1}A_{23}$  is a *Schur complement*.

In other words, in order to invert **A**, we need to execute three steps:

- Invert  $A_{11}$  to form  $A_{11}^{-1}$ .
- Invert  $\mathbf{A}_{22}$  to form  $\mathbf{A}_{22}^{-1}$ .
- Invert  $S_{33} = A_{33} A_{31}A_{11}^{-1}A_{13} A_{32}A_{22}^{-1}A_{23}$ .

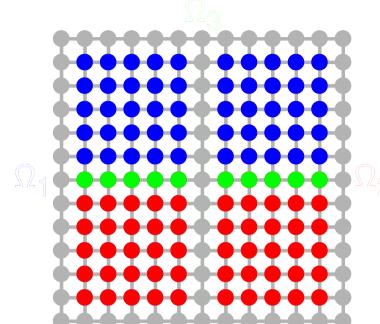

size 
$$\sim N/2 \times N/2$$

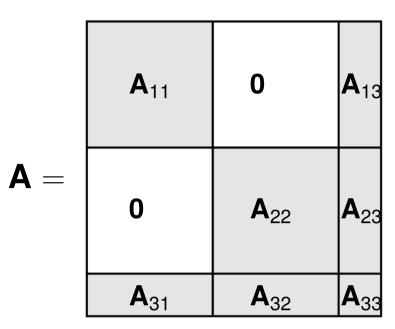

size 
$$\sim N/2 \times N/2$$

size 
$$\sim \sqrt{N} \times \sqrt{N}$$

Notice the obvious recursion!

#### Sparse direct solvers with nested dissection ordering

Typically, nested dissection orderings are more complicated:

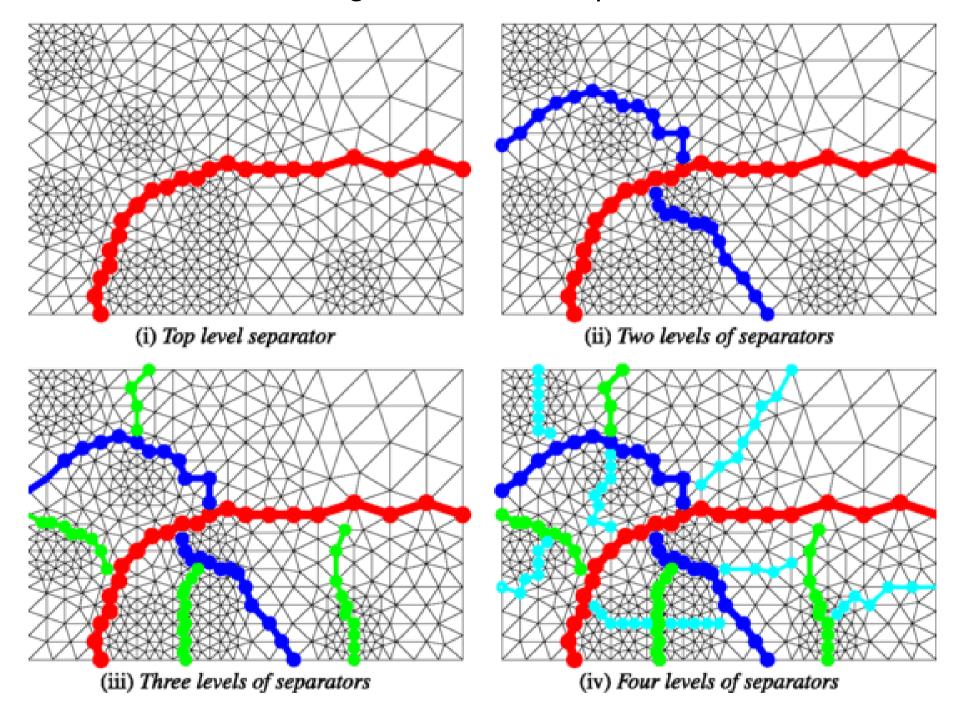

Image credit: Jianlin Xia, "Robust and Efficient Multifrontal Solver for Large Discretized PDEs", 2012

Observe that while the computational domain is 2D in this example, the rank structured matrices all live on the colored 1D domains.

# **Curse of dimensionality: Dimension reduction**

Key point: When faced with a BVP in 3D, you can almost always build direct solvers that rely on dense operator algebra that are defined only 2D domains.

- 1. Constant coefficient problems: Reformulate as integral equation on boundary.
- 2. Variable coefficient problems: Use a sparse direct solver as an "outer" solver.

#### **Outline of talk:**

- Introduction: Problem formulation & solution operators. [Done!]
- Curse of dimensionality. [Done!]
- Interaction ranks why are they small? How small are they?
- Versions of fast direct solvers "strong" versus "weak" etc.
- High order discretizations and fast direct solvers.

Recall that we are interested in solving the PDE 
$$\begin{cases} Au(\mathbf{x}) = g(\mathbf{x}), & \mathbf{x} \in \Omega, \\ Bu(\mathbf{x}) = f(\mathbf{x}), & \mathbf{x} \in \Gamma. \end{cases}$$
 (BVP) Explicit solution formula:  $u(\mathbf{x}) = \int_{\Omega} G(\mathbf{x}, \mathbf{y}) g(\mathbf{y}) d\mathbf{y} + \int_{\Gamma} F(\mathbf{x}, \mathbf{y}) f(\mathbf{y}) dS(\mathbf{y}), & \mathbf{x} \in \Omega. \end{cases}$  (SLN)

Explicit solution formula: 
$$u(\mathbf{x}) = \int_{\Omega} G(\mathbf{x}, \mathbf{y}) g(\mathbf{y}) d\mathbf{y} + \int_{\Gamma} F(\mathbf{x}, \mathbf{y}) f(\mathbf{y}) dS(\mathbf{y}), \qquad \mathbf{x} \in \Omega.$$
 (SLN)

Question: Why do the dense matrices resulting upon discretization of (SLN) typically have off-diagonal blocks of low numerical rank?

(One) Answer: It is a consequence of the *smoothing effect* of elliptic differential equations; it can be interpreted as a *loss of information*.

This effect has many well known physical consequences:

- Rapid convergence of *multipole expansions* when the region of sources is far away from the observation point.
- The St Venant principle in mechanics.
- The inaccuracy of imaging at sub-wavelength scales.
- The intractability of solving the heat equation backwards.

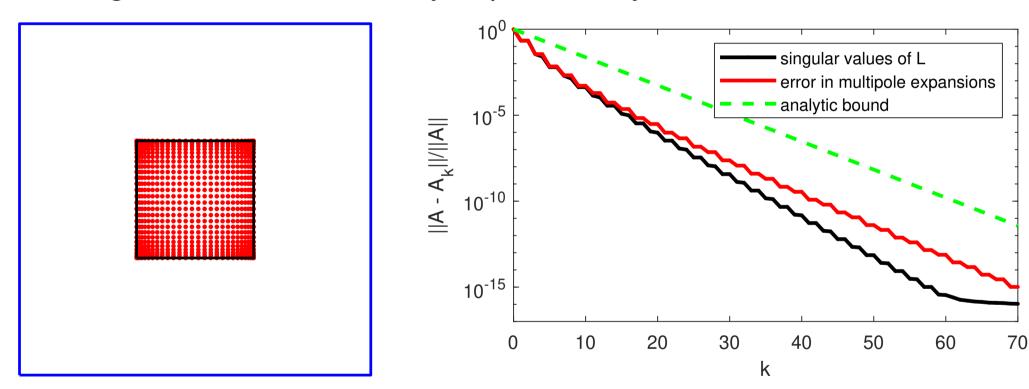

Caveat: High-frequency problems present difficulties — no loss of information for length-scales  $> \lambda$ . Extreme accuracy of optics, high-frequency imaging, etc.

We consider the problem of evaluating an electric field generated by sources in a box: Let  $\Omega_s$  be the red square. It holds a "source" distribution  $\sigma$ .

Let  $\Omega_t$  be the blue square. It holds "target" points where we evaluate the field

$$u(\mathbf{x}) = [L\sigma](\mathbf{x}) = \int_{\Omega_{\mathrm{S}}} \phi(\mathbf{x} - \mathbf{y}) \sigma(\mathbf{x}) \, d\mathbf{y}, \qquad \mathbf{x} \in \Omega_{\mathrm{t}}.$$

Claim: This singular values of L decay exponentially fast.

In this simple case, there is an analytic expansion (a "multipole expansion")

$$\phi(\boldsymbol{x}-\boldsymbol{y}) = \sum_{j=1}^{k} b_j(\boldsymbol{x})c_j(\boldsymbol{y}) + \boldsymbol{E}_k(\boldsymbol{x},\boldsymbol{y}), \qquad \boldsymbol{x} \in \Omega_{\mathrm{t}}, \ \boldsymbol{y} \in \Omega_{\mathrm{s}},$$

for which it is known that  $|E_k(\boldsymbol{x},\boldsymbol{y})| \leq C(\sqrt{2}/3)^{k/2}$ .

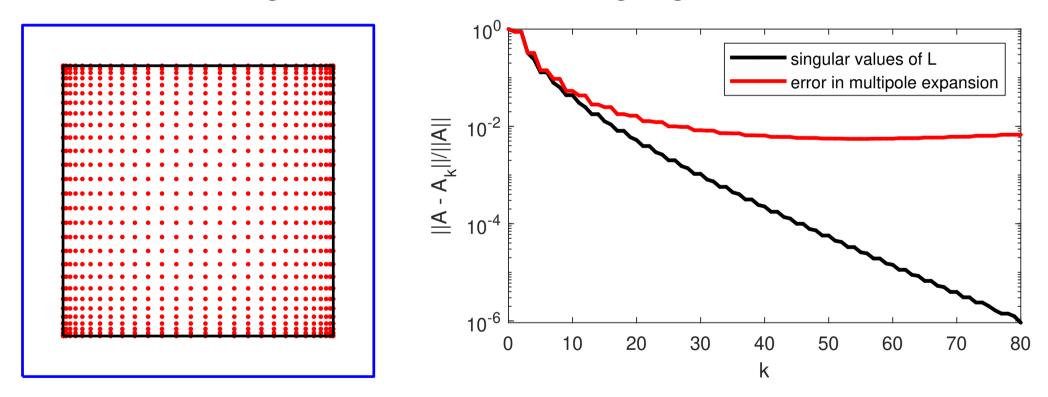

We consider the problem of evaluating an electric field generated by sources in a box: Let  $\Omega_s$  be the red square. It holds a "source" distribution  $\sigma$ .

Let  $\Omega_t$  be the blue square. It holds "target" points where we evaluate the field

$$u(\mathbf{x}) = [L\sigma](\mathbf{x}) = \int_{\Omega_{\mathrm{S}}} \phi(\mathbf{x} - \mathbf{y}) \sigma(\mathbf{x}) \, d\mathbf{y}, \qquad \mathbf{x} \in \Omega_{\mathrm{t}}.$$

The decay depends strongly on the geometry.

In FDS, it is often advantageous to have interacting regions closer:

This situation is harder to analyze — a multipole expansion does not work.

However, numerical compression works very well.

Randomized low rank approximation is particularly helpful.

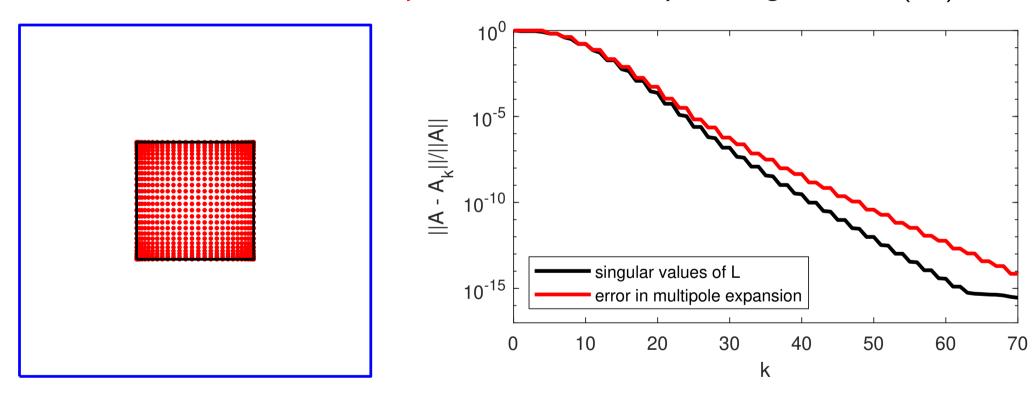

Now let us consider a Helmholtz problem,  $\phi_{\kappa}(\mathbf{x}) = H_0^{(1)}(\kappa |\mathbf{x}|)$ .

Let  $\Omega_{\rm S}$  be the red square. It holds a "source" distribution  $\sigma$ .

Let  $\Omega_t$  be the blue square. It holds "target" points where we evaluate the field

$$oldsymbol{u}(oldsymbol{x}) = [oldsymbol{L}\sigma](oldsymbol{x}) = \int_{\Omega_{\mathrm{S}}} \phi_{\kappa}(oldsymbol{x} - oldsymbol{y}) \sigma(oldsymbol{x}) \, doldsymbol{y}, \qquad oldsymbol{x} \in \Omega_{\mathrm{t}}.$$

We first consider a small Helmholtz parameter, corresponding to diam( $\Omega_s$ ) = 1.6 $\lambda$ .

It looks pretty much like the Laplace problem.

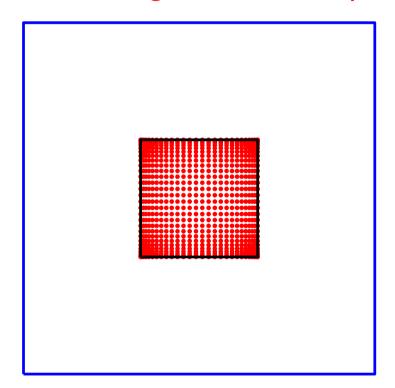

Now let us consider a Helmholtz problem,  $\phi_{\kappa}(\mathbf{x}) = H_0^{(1)}(\kappa |\mathbf{x}|)$ .

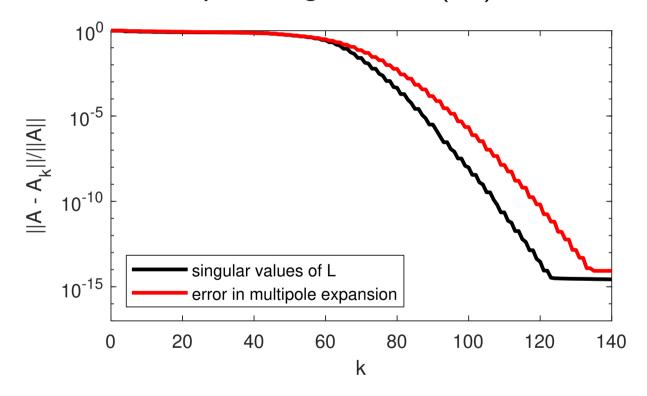

Let  $\Omega_{\rm S}$  be the red square. It holds a "source" distribution  $\sigma$ .

Let  $\Omega_t$  be the blue square. It holds "target" points where we evaluate the field

$$m{u}(m{x}) = [m{L}\sigma](m{x}) = \int_{\Omega_{\mathrm{S}}} \phi_{\kappa}(m{x} - m{y}) \sigma(m{x}) \, dm{y}, \qquad m{x} \in \Omega_{\mathrm{t}}.$$

Now consider a high Helmholtz parameter, corresponding to diam( $\Omega_s$ ) = 11.3 $\lambda$ .

Observe how there is a flat plateau before the singular values start to decay. The plateau reflect the need to resolve all features larger than the wavelength.

Let us consider two simple boundary integral equations on a boundary Γ:

The first is a reformulation of a Dirichlet problem involving the Laplace equation:

$$\alpha \sigma(\mathbf{x}) + \int_{\Gamma} (d(\mathbf{x}, \mathbf{y}) + s(\mathbf{x}, \mathbf{y})) \sigma(\mathbf{y}) ds(\mathbf{y}) = f(\mathbf{x}), \qquad \mathbf{x} \in \Gamma.$$

The second is a reformulation of a Dirichlet problem involving the Helmholtz equation:

$$\beta \sigma(\mathbf{x}) + \int_{\Gamma} (d_{\kappa}(\mathbf{x}, \mathbf{y}) + i\kappa \mathbf{s}_{\kappa}(\mathbf{x}, \mathbf{y})) \ \sigma(\mathbf{y}) \, d\mathbf{s}(\mathbf{y}) = f(\mathbf{x}), \qquad \mathbf{x} \in \Gamma.$$

The kernels are derived from the corresponding fundamental solutions:

$$s(\mathbf{x}, \mathbf{y}) = \phi(\mathbf{x} - \mathbf{y}),$$
 $d(\mathbf{x}, \mathbf{y}) = \partial_{\mathbf{n}(\mathbf{y})} \phi(\mathbf{x} - \mathbf{y}),$ 
 $s_{\kappa}(\mathbf{x}, \mathbf{y}) = \phi_{\kappa}(\mathbf{x} - \mathbf{y}),$ 
 $d_{\kappa}(\mathbf{x}, \mathbf{y}) = \partial_{\mathbf{n}(\mathbf{y})} \phi_{\kappa}(\mathbf{x} - \mathbf{y}),$ 

where, as before,

$$\phi(\mathbf{x}) = -\frac{1}{2\pi} \log |\mathbf{x}|,$$

$$\phi_{\kappa}(\mathbf{x}) = \frac{i}{4} H_0^{(1)}(\kappa |\mathbf{x}|).$$

Let us consider two simple boundary integral equations on a boundary Γ:

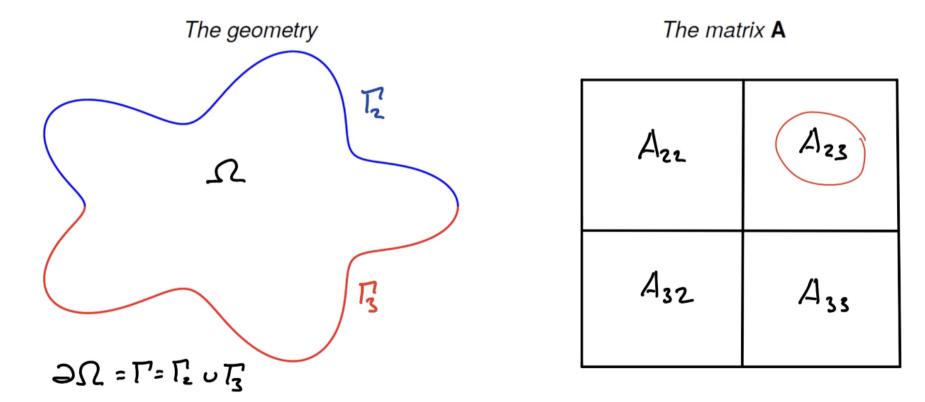

The first is a reformulation of a Dirichlet problem involving the Laplace equation:

$$\alpha \sigma(\mathbf{x}) + \int_{\Gamma} (d(\mathbf{x}, \mathbf{y}) + s(\mathbf{x}, \mathbf{y})) \sigma(\mathbf{y}) ds(\mathbf{y}) = f(\mathbf{x}), \qquad \mathbf{x} \in \Gamma.$$

The second is a reformulation of a Dirichlet problem involving the Helmholtz equation:

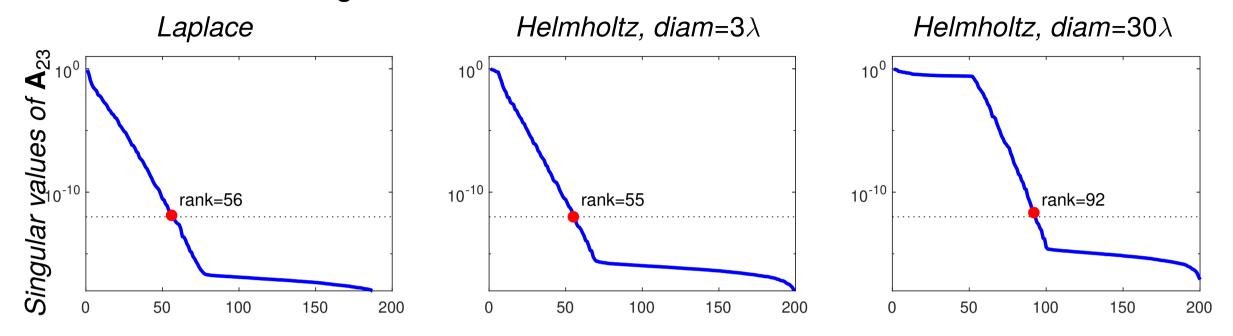

$$\beta \sigma(\mathbf{x}) + \int_{\Gamma} (d_{\kappa}(\mathbf{x}, \mathbf{y}) + i\kappa \mathbf{s}_{\kappa}(\mathbf{x}, \mathbf{y})) \ \sigma(\mathbf{y}) \, d\mathbf{s}(\mathbf{y}) = f(\mathbf{x}), \qquad \mathbf{x} \in \Gamma.$$

Let A denote the matrix resulting from discretization of either BIE.

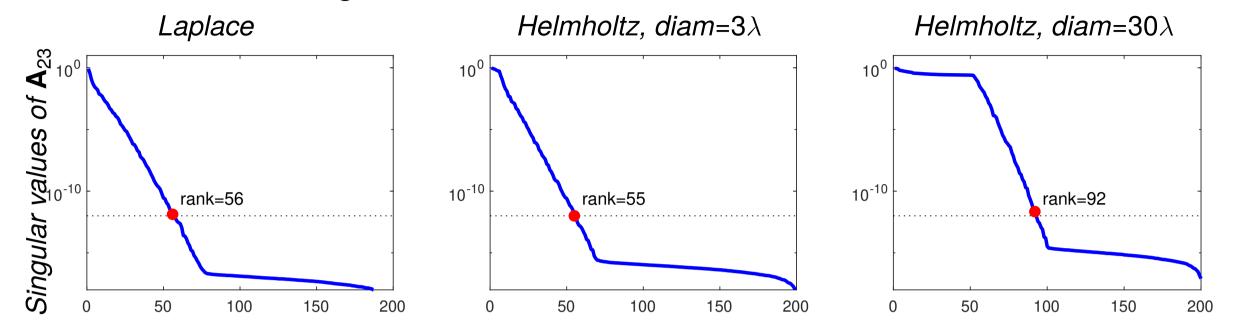

On the next slide, we show the singular values of the off-diagonal block  $A_{23}$ .

The ranks of an off-diagonal block of **A**:

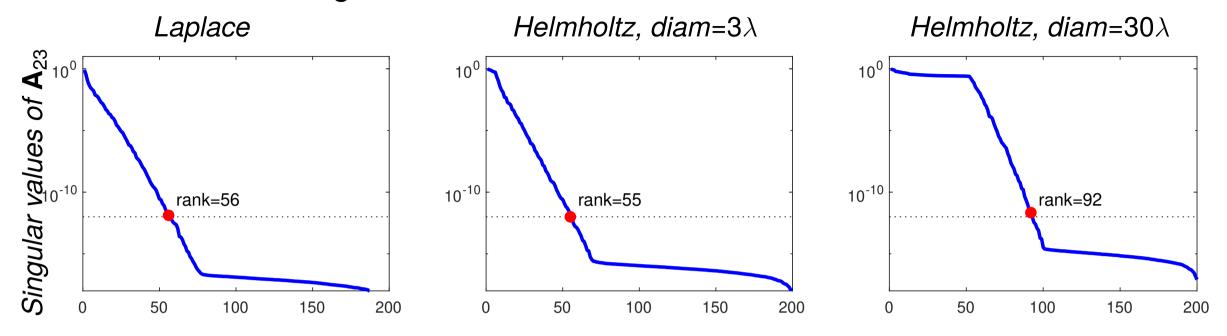

This is all as expected. Can be proven directly from properties of the kernels.

The ranks of an off-diagonal block of **A**:

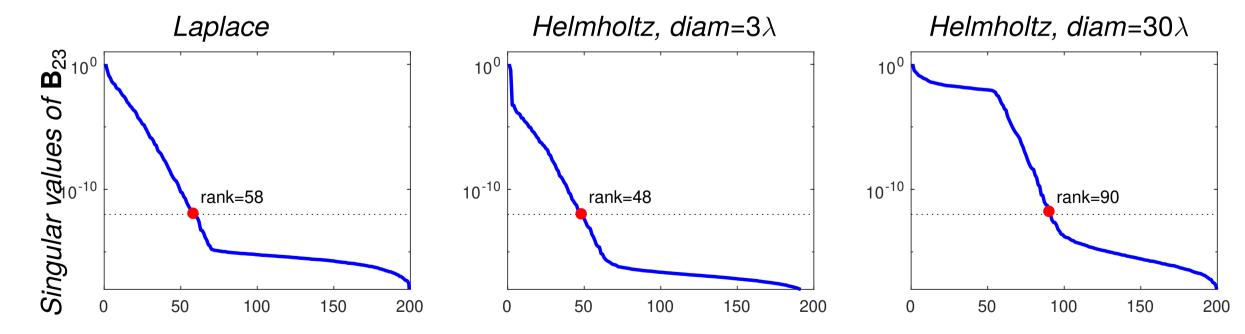

This is all as expected. Can be proven directly from properties of the kernels. Now the fun part! We set  ${\bf B}={\bf A}^{-1}$ , and plot the svds of the off-diagonal block  ${\bf B}_{23}$ .

The ranks of an off-diagonal block of **A**:

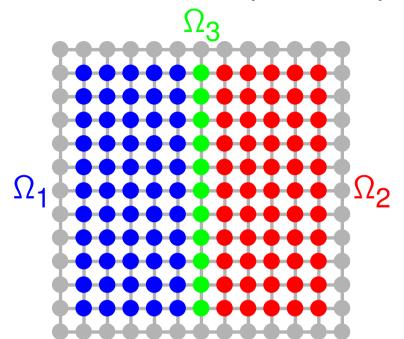

This is all as expected. Can be proven directly from properties of the kernels. Now the fun part! We set  $\mathbf{B} = \mathbf{A}^{-1}$ , and plot the svds of the off-diagonal block  $\mathbf{B}_{23}$ .

Remarkable similarity!
(Observe ill-conditioning due to close resonances for the Helmholtz BIE.)

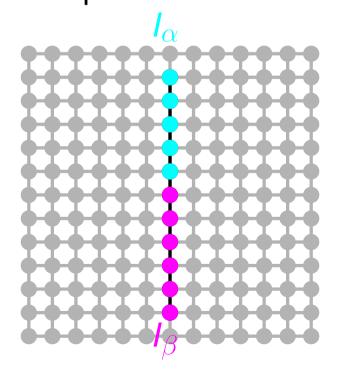

#### Interaction ranks: Stiffness matrix from finite difference discretization

Recall our example of Laplace's equation discretized using the 5-point stencil.

	<b>A</b> <sub>11</sub>	0	<b>A</b> 13
<b>A</b> =	0	<b>A</b> <sub>22</sub>	<b>A</b> 23
	<b>A</b> <sub>31</sub>	<b>A</b> <sub>32</sub>	<b>A</b> <sub>33</sub>

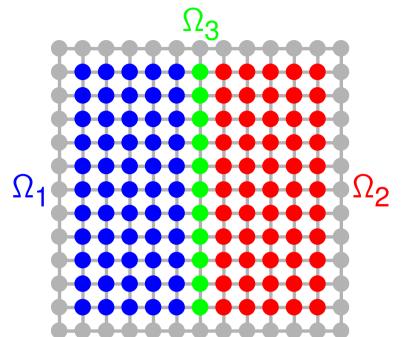

We build the Schur complement  $\mathbf{S} = \mathbf{A}_{33} - \mathbf{A}_{31}\mathbf{A}_{11}^{-1}\mathbf{A}_{13} - \mathbf{A}_{32}\mathbf{A}_{22}^{-1}\mathbf{A}_{23}$ . Then split the Schur complement into four parts:

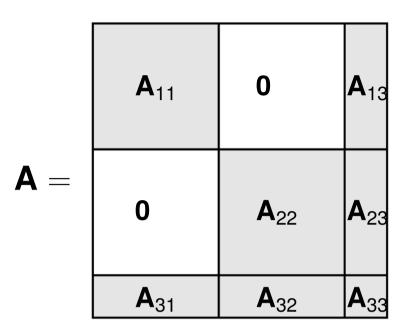

We explore the svds of  $\mathbf{S}_{\alpha\beta}$  — encoding interactions between  $\mathbf{I}_{\alpha}$  and  $\mathbf{I}_{\beta}$ .

#### Interaction ranks: Stiffness matrix from finite difference discretization

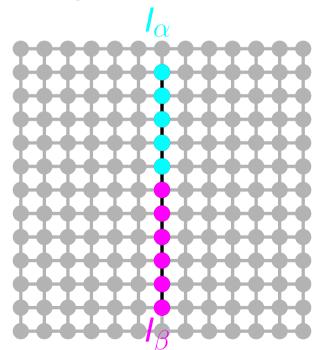

Recall our example of Laplace's equation discretized using the 5-point stencil.

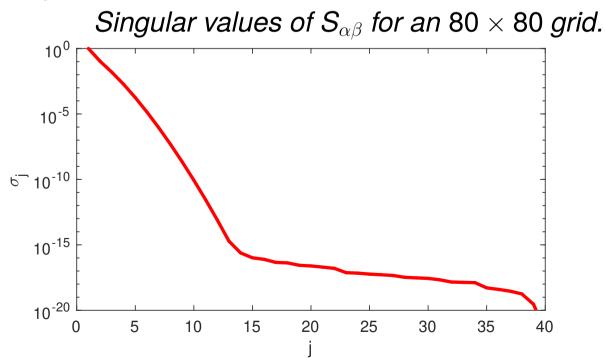

We build the Schur complement  $\mathbf{S} = \mathbf{A}_{33} - \mathbf{A}_{31} \mathbf{A}_{11}^{-1} \mathbf{A}_{13} - \mathbf{A}_{32} \mathbf{A}_{22}^{-1} \mathbf{A}_{23}$ .

Then split the Schur complement into four parts:

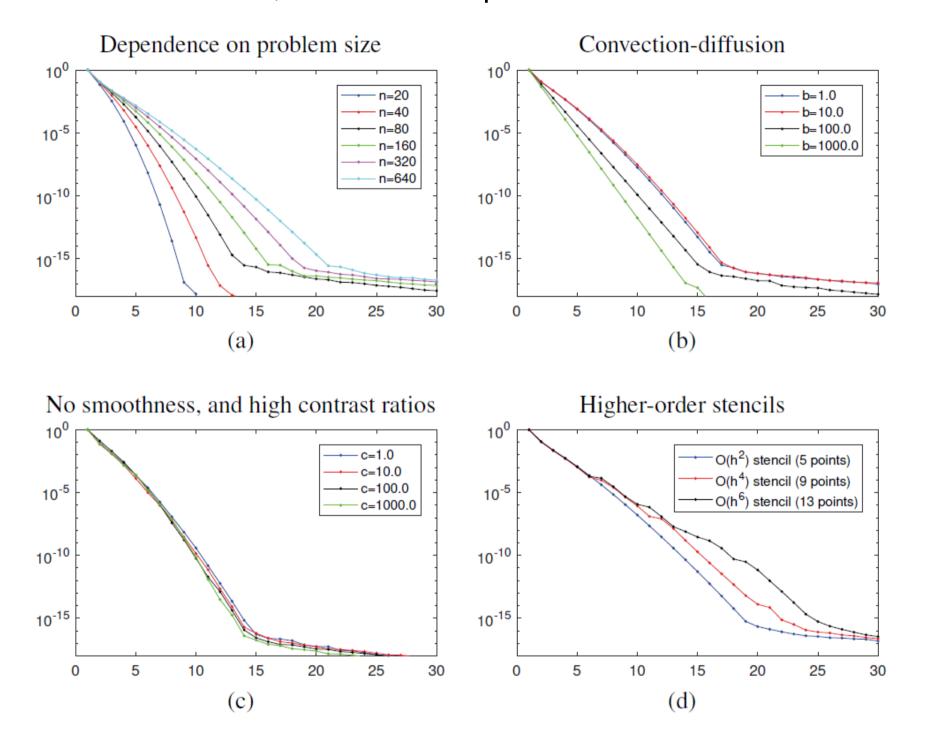

We explore the svds of  $\mathbf{S}_{\alpha\beta}$  — encoding interactions between  $\mathbf{I}_{\alpha}$  and  $\mathbf{I}_{\beta}$ .

#### Interaction ranks: Stiffness matrix from finite difference discretization

Let us try a few different PDEs, and different problem sizes:

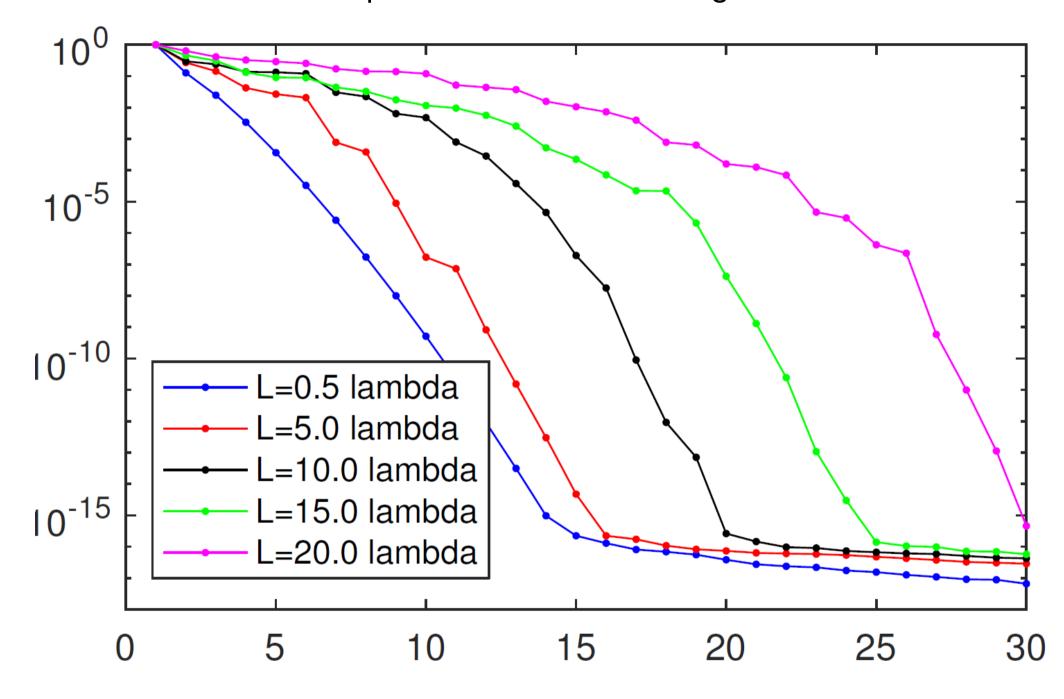

Note: The rank decay property is remarkably stable!

Note: The decay continues to  $\epsilon_{\rm mach}$  — regardless of the discretization errors!

Next, let us consider Helmholtz problems with increasing wave numbers.

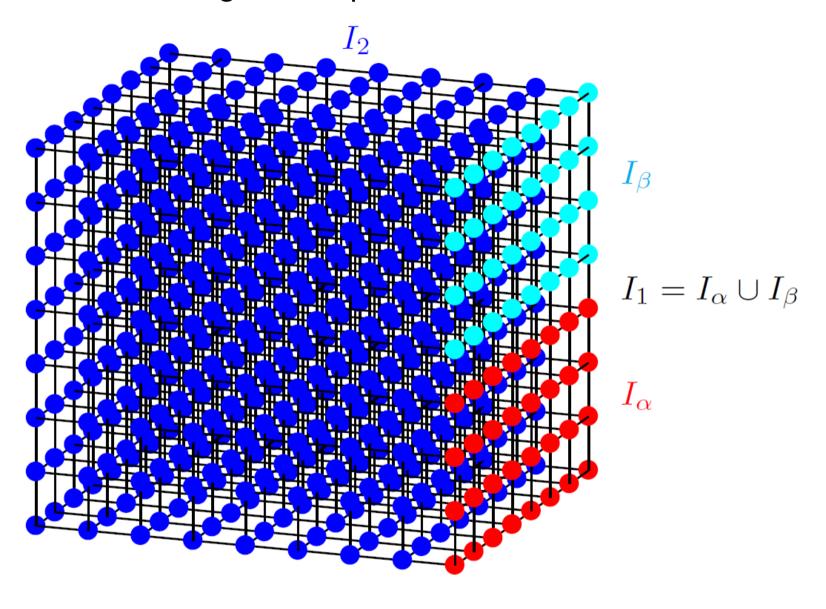

Next, let us consider Helmholtz problems with increasing wave numbers.

We recognize this pattern from the potential evaluation operator:

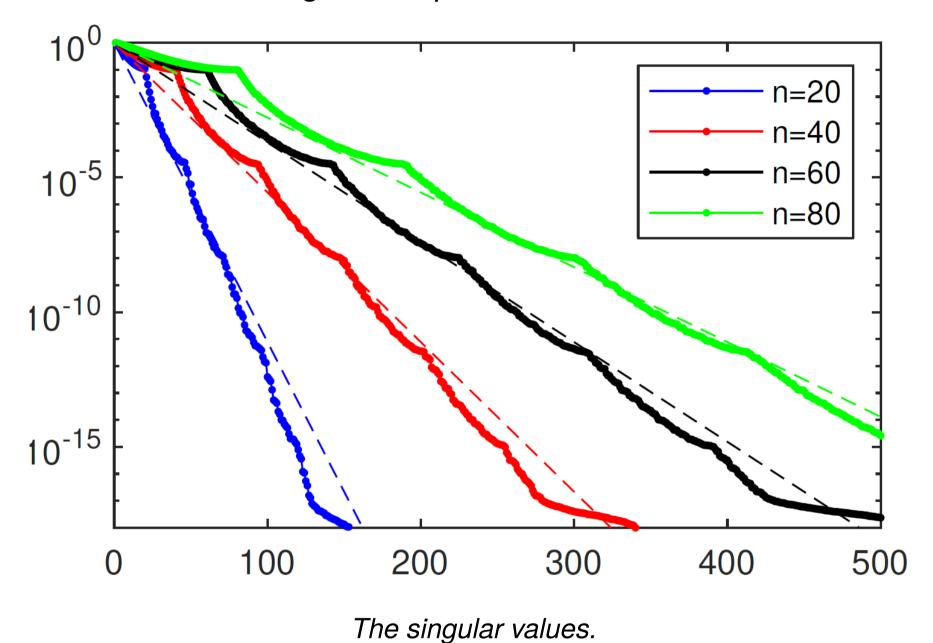

Fast decay once oscillations are resolved.

Finally, let us consider the analogous 3D problem.

The geometry.

Finally, let us consider the analogous 3D problem.

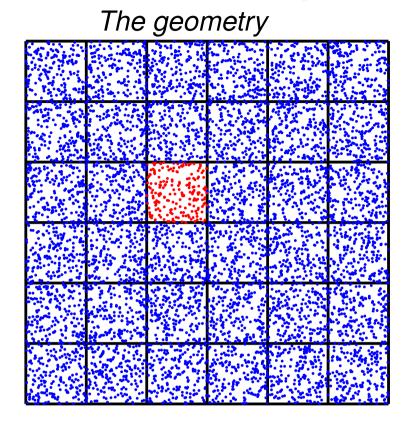

#### **Outline of talk:**

- Introduction: Problem formulation & solution operators. [Done!]
- Curse of dimensionality. [Done!]
- Interaction ranks why are they small? How small are they? [Done!]
- Versions of fast direct solvers "strong" versus "weak" etc.
- High order discretizations and fast direct solvers.

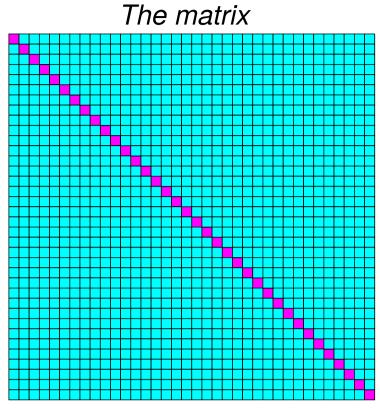

## Versions of fast direct solvers: "strong" versus "weak" admissibility

Weak admissibility: Compress directly adjacent patches.

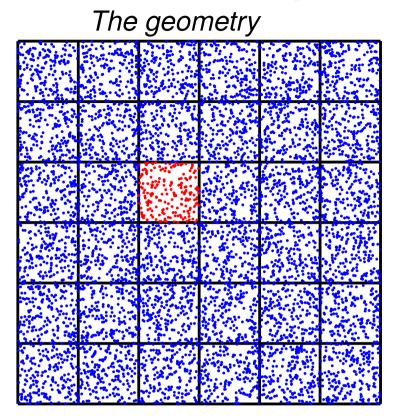

Left: Points in a box  $\Omega = [0, 1]^2$ . Red sources induce potentials on blue points. Average rank=13.9 at  $\varepsilon = 10^{-8}$ .

Right: Magenta blocks are dense. Cyan blocks low rank. Many low rank blocks, but high ranks.

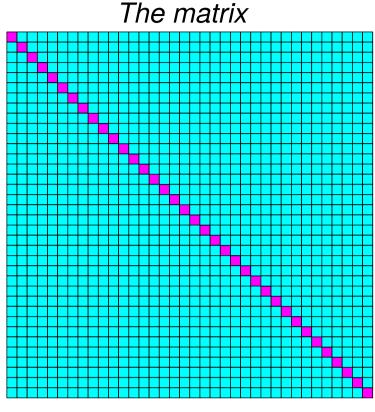

# Versions of fast direct solvers: "strong" versus "weak" admissibility

Weak admissibility: Compress directly adjacent patches.

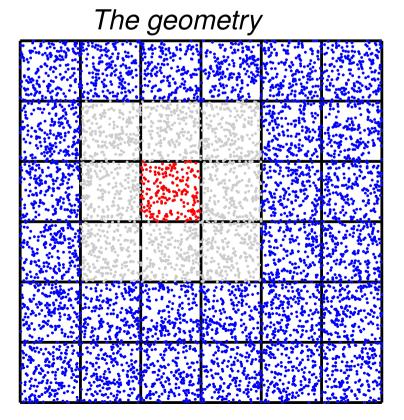

Left: Points in a box  $\Omega = [0, 1]^2$ . Red sources induce potentials on blue points. Average rank=13.9 at  $\varepsilon = 10^{-8}$ .

Right: Magenta blocks are dense. Cyan blocks low rank. Many low rank blocks, but high ranks.

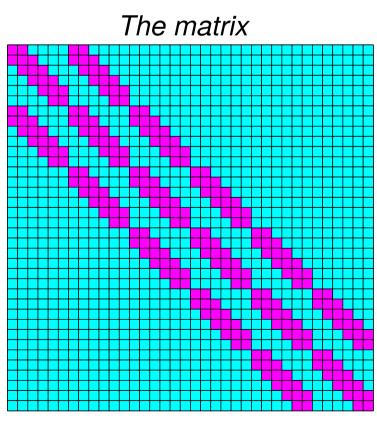

Strong admissibility: Compress only "far-field" interactions.

Left: Points in a box  $\Omega = [0, 1]^2$ . Red sources induce potentials on blue points. Average rank=7.7 at  $\varepsilon = 10^{-8}$ .

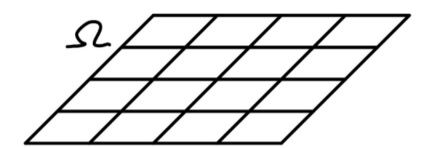

Right: Magenta blocks are dense. Cyan blocks low rank. More dense blocks, but lower ranks.

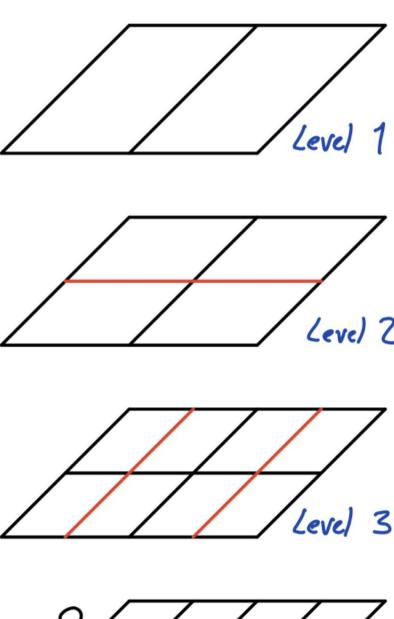

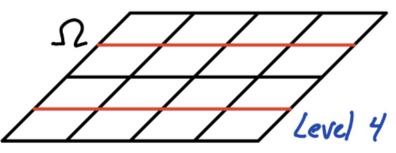

# Versions of fast direct solvers: "flat" versus "hierarchical" tessellations Flat tessellations Hierarchical tessellations

Use a single tessellation of the domain.

Use a hierarchy of tessellations.

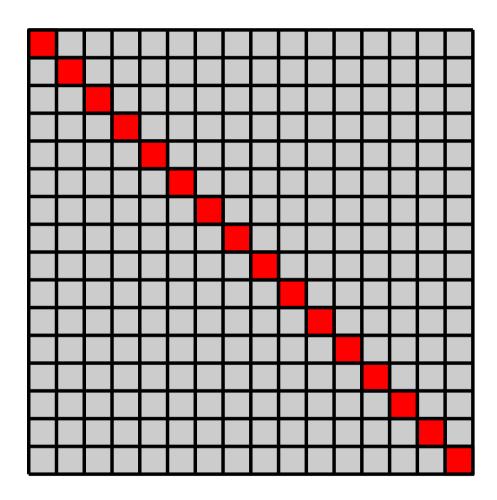

# Versions of fast direct solvers: "flat" versus "hierarchical" tessellations

#### Flat tessellations

Use a single tessellation of the domain.

The resulting matrix:

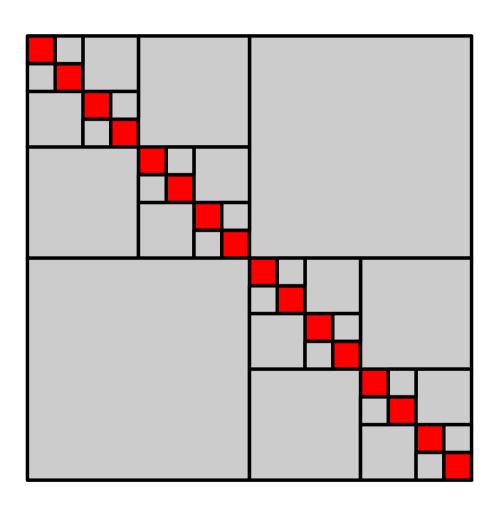

Easy to work with.

Sometimes "good enough".

#### **Hierarchical tessellations**

Use a hierarchy of tessellations.

The resulting matrix:

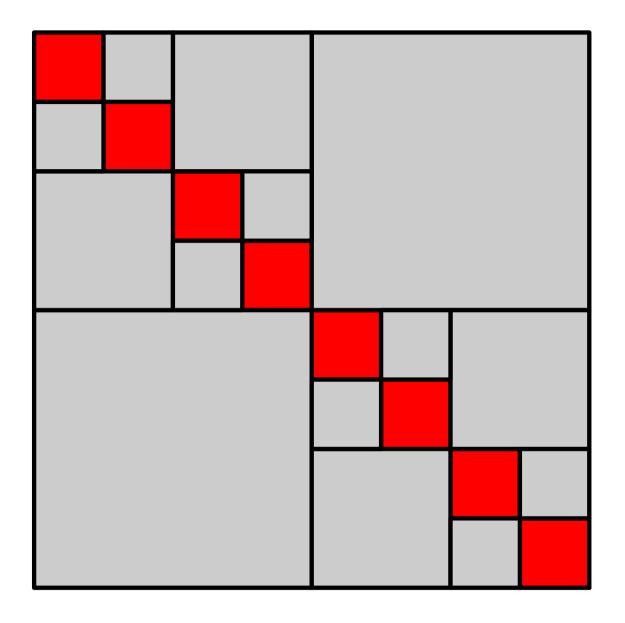

More complicated to code and analyze.

Better asympt. complexity (can be linear).

## Versions of fast direct solvers: "nested" versus "general" bases

General bases: Let us consider a basic rank structured matrix:

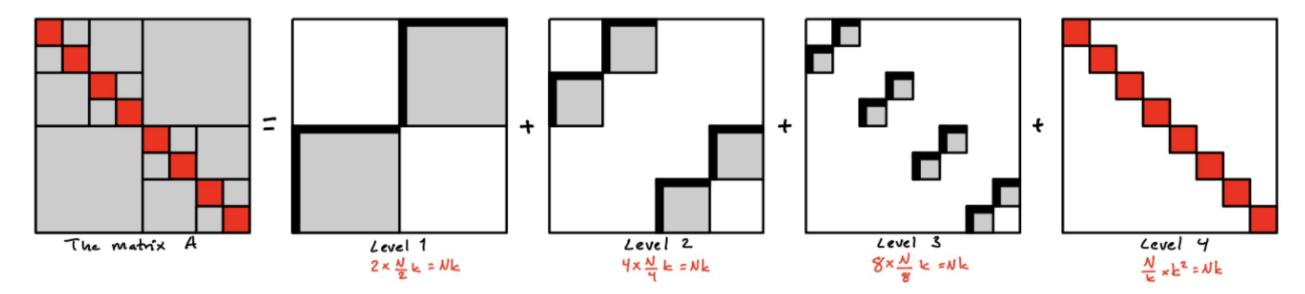

Question: How much storage is required?

## Versions of fast direct solvers: "nested" versus "general" bases

**General bases:** Let us consider a basic rank structured matrix:

Observe that you can view the matrix as a *sum* over different "levels":

Let *k* denote the rank of the off-diagonal blocks.

At each level, the cost to store the factors is  $\sim Nk$ .

There are  $\sim \log(N)$  levels, so total storage  $\sim kN \log(N)$ .

### Versions of fast direct solvers: "nested" versus "general" bases

Nested bases: These were introduced to eliminate log-factors, and improve efficiency.

The idea is to define the low rank factors for the off-diagonal blocks *recursively* 

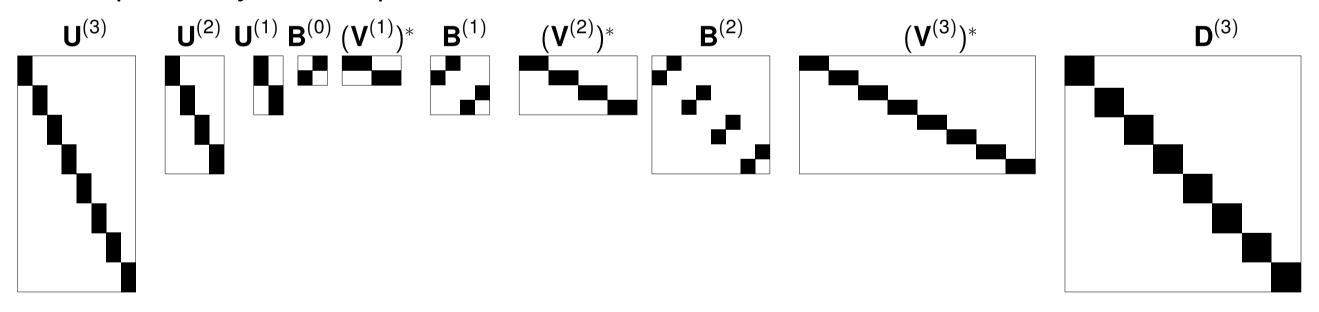

— the bases on one level are defined in terms of the bases on the next finer level.

Formally, this leads to a *multiplicative* representation, rather than an *additive* one.

For instance, it could take the form

$$\mathbf{A} = \mathbf{U}^{(3)} \big( \mathbf{U}^{(2)} \big( \mathbf{U}^{(1)} \, \mathbf{B}^{(0)} \, (\mathbf{V}^{(1)})^* + \mathbf{B}^{(1)} \big) (\mathbf{V}^{(2)})^* + \mathbf{B}^{(2)} \big) (\mathbf{V}^{(3)})^* + \mathbf{D}^{(3)},$$

where pictorially, the shapes of the factors are as follows:

The cost to store level  $\ell$  is now  $2^{-\ell}Nk \rightarrow \text{geometric sum and } O(kN)$  total storage.

Note: The classical Fast Multipole Method relies on nested bases.

This is in contrast to Barnes-Hut which (implicitly) uses general bases.

#### **Versions of fast direct solvers:**

We can now loosely organize some common rank-structured matrix "formats":

	Flat	Hierarchical		
		General bases	Nested bases	
Weak	Block Separable	Hierarchically off-diagonal	Hierarchically Block Sep-	
admissi-		low rank (HODLR)	arable (HBS/HSS); recur-	
bility			sive skeletonization	
Strong	Block Low Rank	${\cal H}$ -matrices; Barnes-Hut	$\mathcal{H}^2$ -matrices; Fast Multi-	
admissi-			pole Method; strong recur-	
bility			sive skeletonization	

Complexity of implementation *increases* as you go down and to the right in the table. Asymptotic flop count *decreases* as you go down and to the right in the table. The higher the dimension, the more complex scheme you need to use.

Recommendation: Use the simplest format that gives acceptable computational cost.

**Note:** In principle, the term "H-matrix" is extremely broad — every other format is a special case. However, the table reflects the standard usage of the term.

Claim: Direct solvers are ideal for combining with high order discretization.

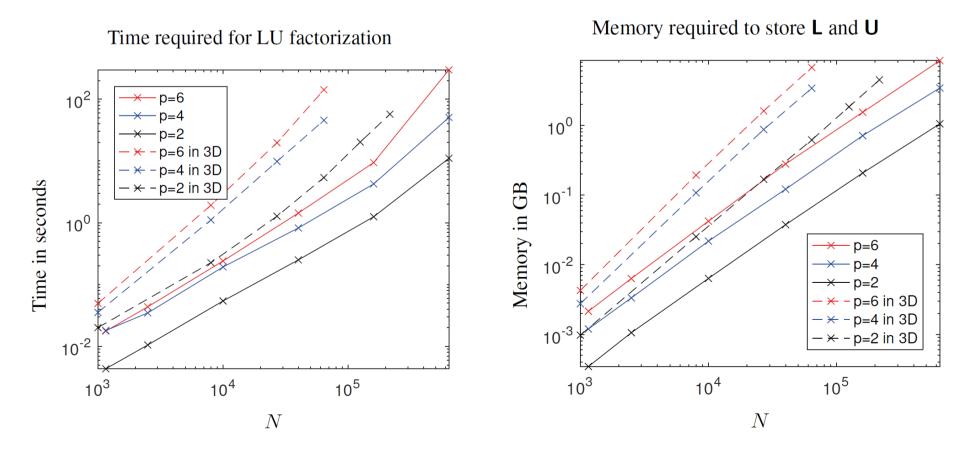

- Direct solvers use a lot of memory per degree of freedom.
  - → You want to maximize the oomph per DOF.
- Direct solvers are particularly well suited for "high" frequency wave problems.
  - → Need high accuracy due to ill-conditioned physics.
- High order methods sometimes lead to more ill-conditioned systems.
  - → Can be hard to get iterative solvers to converge.

**Problem:** If you combine "nested dissection" with traditional discretization techniques (FD, FEM, etc), then the performance *plummets* as the order is increased.

Solution: Pick your discretization scheme carefully!

- When discretizing the PDE, use methods that play well with "static condensation".
   You want a clean separation between "interior" and "edge" degrees of freedom.
  - Multidomain spectral collocation methods ("HPS", "ultraSEM", etc.).
  - Discontinuous Galerkin. (I think.)
- When integral equation formulations are used, pick quadratures that have as localized "corrections" as possible. (Very technical point here!)

As a numerical illustration, let us consider the "Hierarchical Poincaré-Steklov (HPS)" method. We set  $\Omega = [0, 1]^2$  and  $\Gamma = \partial \Omega$ , and consider the problem

$$\begin{cases} -\Delta u(\mathbf{x}) - \kappa^2 u(\mathbf{x}) = 0, & \mathbf{x} \in \Omega, \\ u(\mathbf{x}) = f(\mathbf{x}), & \mathbf{x} \in \Gamma. \end{cases}$$

We discretize using spectral collocation on a composite grid on  $\Omega$  (Chebyshev nodes):

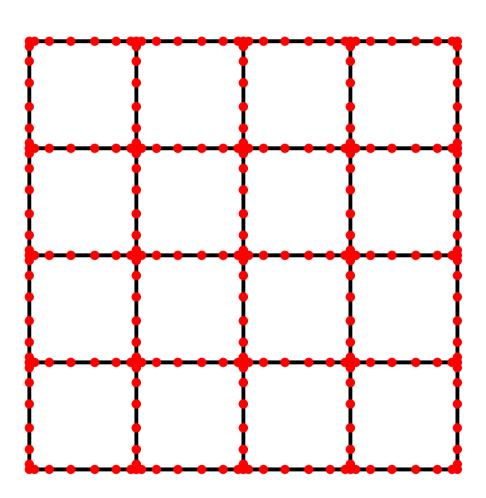

On patch boundaries, we enforce continuity of the potential and the normal derivative. (See talks by Chen and Fortunato in MS31 for details.)

Error is measured in sup-norm:  $e = \max_{\mathbf{x} \in \Omega} |u(\mathbf{x}) - u_{\text{exact}}(\mathbf{x})|$ .

Note: The times refer to a simple Matlab implementation executed on a \$1k laptop.

Note: Fixed number of points per wave-length. Almost no "pollution error"!

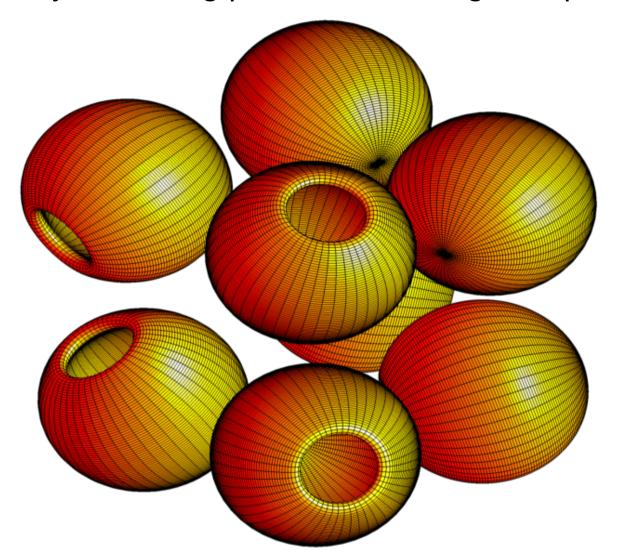

By incorporating rank-structured matrix algebra for the Schur complements, we can access larger problem sizes, and get linear scaling in important cases.

(About six accurate digits in solution.)

## **Boundary integral equations**

Let us consider a multibody scattering problem involving multiple cavities:

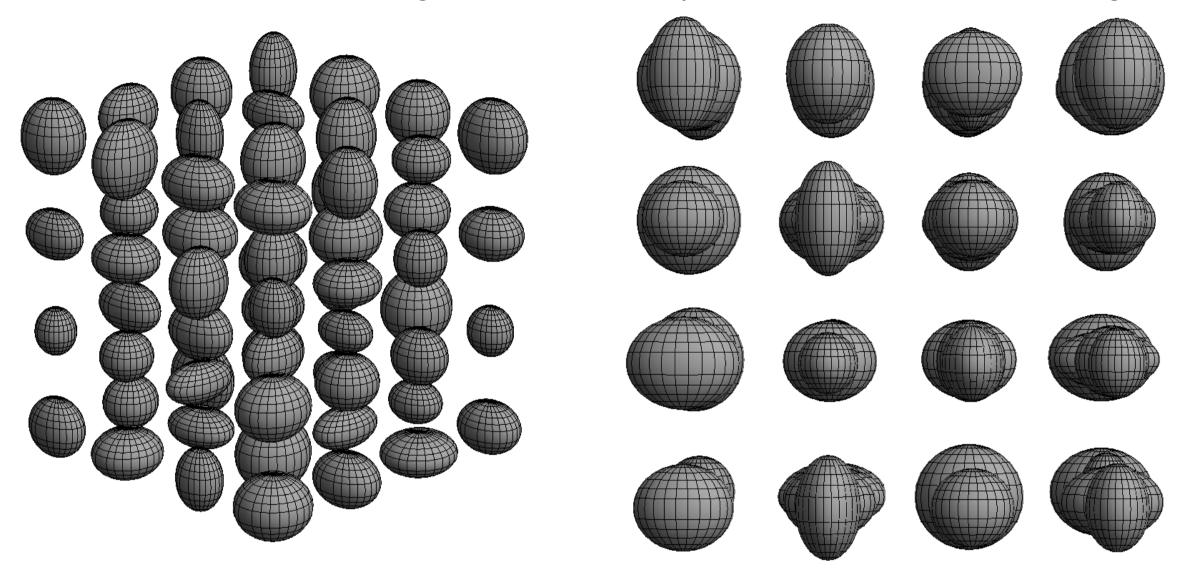

Acoustic scattering on the exterior domain. Each bowl is about  $5\lambda$ .

A hybrid direct/iterative solver is used (a highly accurate scattering matrix is computed for each body). On an office desktop, we achieved an accuracy of  $10^{-5}$ , in about 6h (essentially all the time is spent in applying the inter-body interactions via the Fast Multipole Method). Accuracy  $10^{-7}$  took 27h. [2015, CAMWA, Hao/M./Young]

## **Boundary integral equations**

Consider sound-soft scattering from a multi-body scatterer of size 4 wave-lengths:

The global scattering matrix is computed using the hierarchical direct solver described. (The ellipsoids are not rotationally symmetric.)

## **Boundary integral equations**

The local truncation error is set to  $10^{-3}$ .

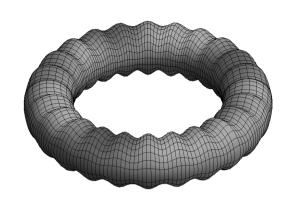

Grid dimensions	N	T	Ratio	Predicted
$2 \times 2 \times 2$	12288	$1.02 \times 10^{+1} \ 3.37 \times 10^{-04}$	-	-
$3 \times 3 \times 3$	41 472	$\left  3.43 \times 10^{+1} \right  4.81 \times 10^{-04}$	3.4	6.2
$4 \times 4 \times 4$	98 304	$\left  7.92 \times 10^{+1} \right  1.57 \times 10^{-04}$	2.3	3.7
$6 \times 6 \times 6$	331 776	$\left 2.96 \times 10^{+2} \right  7.03 \times 10^{-04}$	3.7	6.2
$8 \times 8 \times 8$	786 432	$\left 6.70\times10^{+2}\right 4.70\times10^{-04}$	2.3	3.7
10 × 10 × 10	1 536 000	$2.46 \times 10^{+3} \ 3.53 \times 10^{-04}$	3.7	2.7

Increasing the accuracy is possible, but comes at a cost.

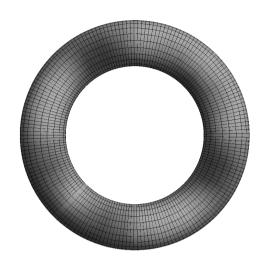

Now the local truncation error is set to  $10^{-6}$ .

Grid dimensions	N	T	Ratio	Predicted
$2 \times 2 \times 2$	49 152	$1.61 \times 10^{+2} \ 1.22 \times 10^{-07}$	_	-
$3 \times 3 \times 3$	165 888	$\left 6.87\times10^{+2}\right 4.92\times10^{-07}$	4.3	6.2
$4 \times 4 \times 4$	393 216	$\left  1.68 \times 10^{+3} \right  5.31 \times 10^{-07}$	2.4	3.6

8 × 8 × 8	3 145 728	$\left  1.59 \times 10^{+4} \right  2.30 \times 10^{-07}$	2.4	3.6

## **Boundary integral equations**

The domain is roughly  $2 \times 2 \times 0.7$  wave-lengths in size.

<b>N</b> triangles	N	T	E
32	1 664	$7.16 \times 10^{+00}$	$3.51 \times 10^{-02}$
128	6 6 5 6	$6.29 \times 10^{+01}$	$4.41 \times 10^{-03}$
512	26 624	$2.81 \times 10^{+02}$	$4.08 \times 10^{-05}$
			$7.80 \times 10^{-07}$
8 192	425 984	$1.47 \times 10^{+04}$	$3.25 \times 10^{-08}$

(Note: Laplace problems are much faster.)

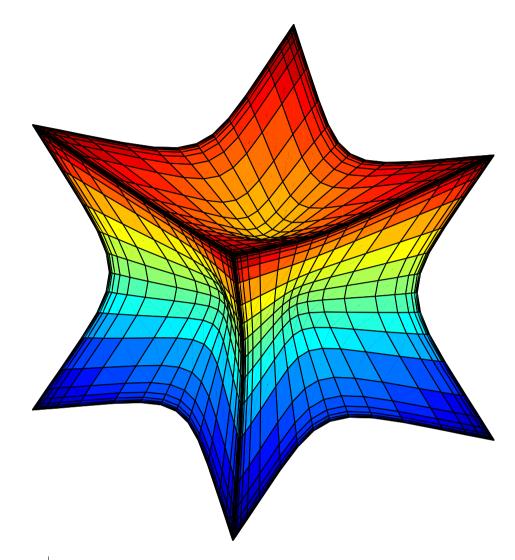

### **Boundary integral equations**

A surface  $\Gamma$  with corners and edges.

The grid has been refined to attain high accuracy.

Computing scattering matrices for the corners is conceptually easy (but laborious). The direct solver eliminates "extra" DOFs.

Compressing the edges takes effort!

$N_{tris}$	N	E	$\mathcal{T}$	$N_{ m out}  imes N_{ m in}$
192	21 504	$2.60 \times 10^{-08}$	$6.11 \times 10^{+02}$	617 × 712
432	48 384	$2.13 \times 10^{-09}$	$1.65 \times 10^{+03}$	620 × 694
768	86 016	$3.13 \times 10^{-10}$	$3.58 \times 10^{+03}$	612 × 685

Results from a Helmholtz problem (acoustic scattering) on the domain exterior to the "edgy" cube. The domain is about 3.5 wave-lengths in diameter.

"FEM-BEM coupling"

Consider the free space acoustic scattering problem

$$\begin{cases} -\Delta u(\boldsymbol{x}) - \kappa^2 (1 - b(\boldsymbol{x})) u(\boldsymbol{x}) = -\kappa^2 b(\boldsymbol{x}) v(\boldsymbol{x}), & \boldsymbol{x} \in \mathbb{R}^2 \\ \lim_{|\boldsymbol{x}| \to \infty} \sqrt{|\boldsymbol{x}|} (\partial_{|\boldsymbol{x}|} u(\boldsymbol{x}) - i\kappa u(\boldsymbol{x})) = 0, \end{cases}$$

#### where

- b is a smooth scattering potential with compact support, where
- *v* is a given "incoming potential" and where
- u is the sought "outgoing potential."

$$-\Delta u - \kappa^2 (1-b) u = -\kappa^2 b v$$

$$Support(b)$$

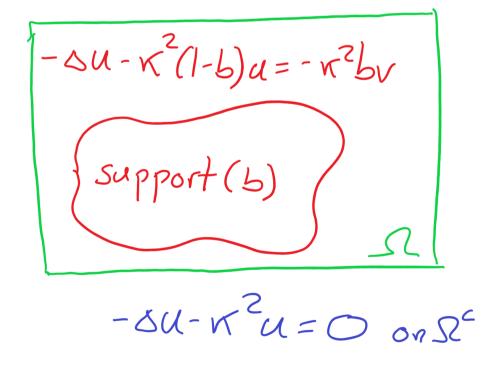

"FEM-BEM coupling"

Consider the free space acoustic scattering problem

$$\begin{cases} -\Delta u(\boldsymbol{x}) - \kappa^2 (1 - b(\boldsymbol{x})) u(\boldsymbol{x}) = -\kappa^2 b(\boldsymbol{x}) v(\boldsymbol{x}), & \boldsymbol{x} \in \mathbb{R}^2 \\ \lim_{|\boldsymbol{x}| \to \infty} \sqrt{|\boldsymbol{x}|} (\partial_{|\boldsymbol{x}|} u(\boldsymbol{x}) - i\kappa u(\boldsymbol{x})) = 0, \end{cases}$$

#### where

- b is a smooth scattering potential with compact support, where
- *v* is a given "incoming potential" and where
- *u* is the sought "outgoing potential."

Introduce an artificial box  $\Omega$  such that support(b)  $\subseteq \Omega$ .

Joint work with A. Barnett and A. Gillman.

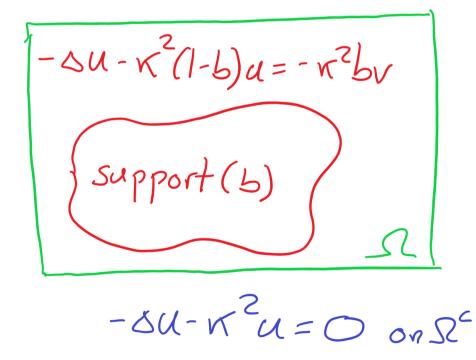

"FEM-BEM coupling"

Consider the free space acoustic scattering problem

$$\begin{cases} -\Delta u(\mathbf{x}) - \kappa^2 (1 - b(\mathbf{x})) u(\mathbf{x}) = -\kappa^2 b(\mathbf{x}) v(\mathbf{x}), & \mathbf{x} \in \mathbb{R}^2 \\ \lim_{|\mathbf{x}| \to \infty} \sqrt{|\mathbf{x}|} (\partial_{|\mathbf{x}|} u(\mathbf{x}) - i\kappa u(\mathbf{x})) = 0, \end{cases}$$

#### where

- b is a smooth scattering potential with compact support, where
- *v* is a given "incoming potential" and where
- *u* is the sought "outgoing potential."

Introduce an artificial box  $\Omega$  such that support(b)  $\subseteq \Omega$ .

On  $\Omega$ :

Variable coefficient PDE.
 Constant coefficient PDE.

# "FEM-BEM coupling"

$$\begin{cases} -\Delta u_{\text{out}}(\boldsymbol{x}) - \kappa^2 (1 - b(\boldsymbol{x})) u_{\text{out}}(\boldsymbol{x}) = -\kappa^2 b(\boldsymbol{x}) u_{\text{in}}(\boldsymbol{x}) \\ \lim_{|\boldsymbol{x}| \to \infty} \sqrt{|\boldsymbol{x}|} (\partial_{|\boldsymbol{x}|} u_{\text{out}}(\boldsymbol{x}) - i\kappa u_{\text{out}}(\boldsymbol{x})) = 0 \end{cases}$$

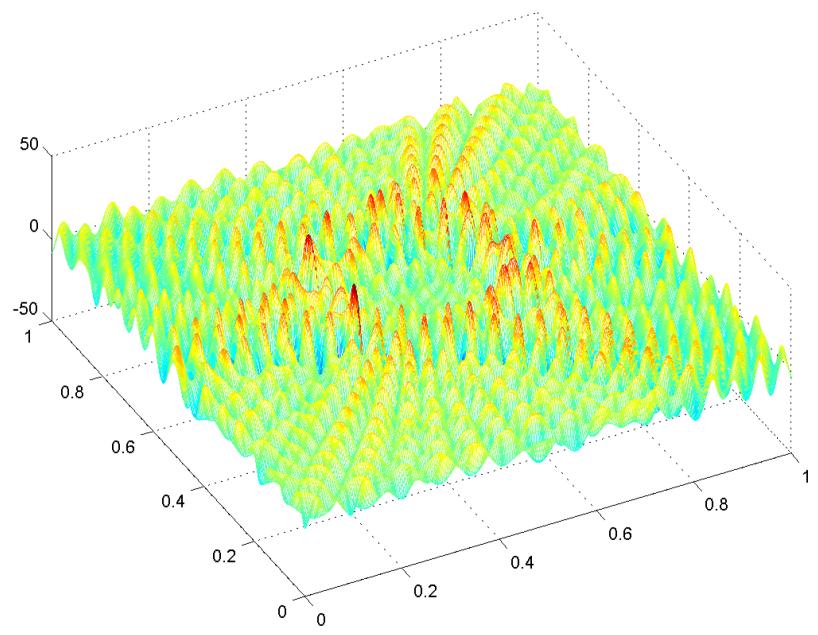

## The scattering potential b

## 'FEM-BEM coupling"

$$\begin{cases} -\Delta u_{\text{out}}(\boldsymbol{x}) - \kappa^2 (1 - b(\boldsymbol{x})) u_{\text{out}}(\boldsymbol{x}) = -\kappa^2 b(\boldsymbol{x}) u_{\text{in}}(\boldsymbol{x}) \\ \lim_{|\boldsymbol{x}| \to \infty} \sqrt{|\boldsymbol{x}|} (\partial_{|\boldsymbol{x}|} u_{\text{out}}(\boldsymbol{x}) - i\kappa u_{\text{out}}(\boldsymbol{x})) = 0 \end{cases}$$

The outgoing field  $u_{\text{out}}$  (resulting from an incoming plane wave  $u_{\text{in}}(x) = \cos(\kappa x_1)$ )

$$N = 231361$$

$$T_{\rm build} = 7.2 \text{ sec}$$

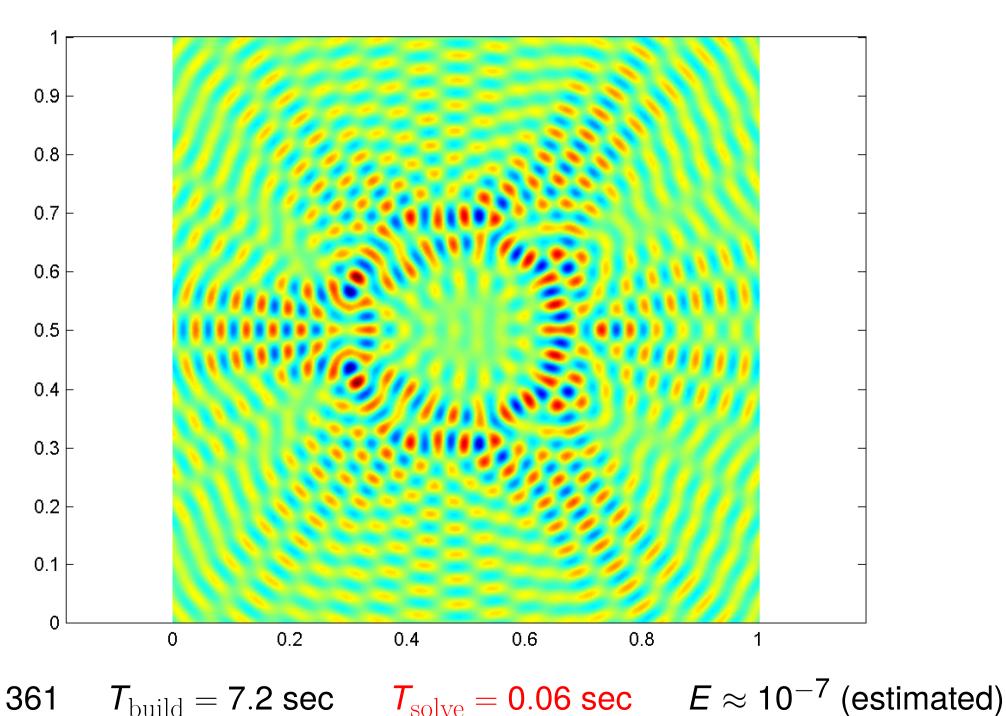

$$T_{
m solve} = 0.06~{
m sec}$$

$$T_{\rm build} = 7.2~{\rm sec}$$
  $T_{\rm solve} = 0.06~{\rm sec}$   $E \approx 10^{-7}~{\rm (estimated)}$ 

N = 231361

$$\begin{cases} -\Delta u_{\text{out}}(\boldsymbol{x}) - \kappa^2 (1 - b(\boldsymbol{x})) u_{\text{out}}(\boldsymbol{x}) = -\kappa^2 b(\boldsymbol{x}) u_{\text{in}}(\boldsymbol{x}) \\ \lim_{|\boldsymbol{x}| \to \infty} \sqrt{|\boldsymbol{x}|} (\partial_{|\boldsymbol{x}|} u_{\text{out}}(\boldsymbol{x}) - i\kappa u_{\text{out}}(\boldsymbol{x})) = 0 \end{cases}$$

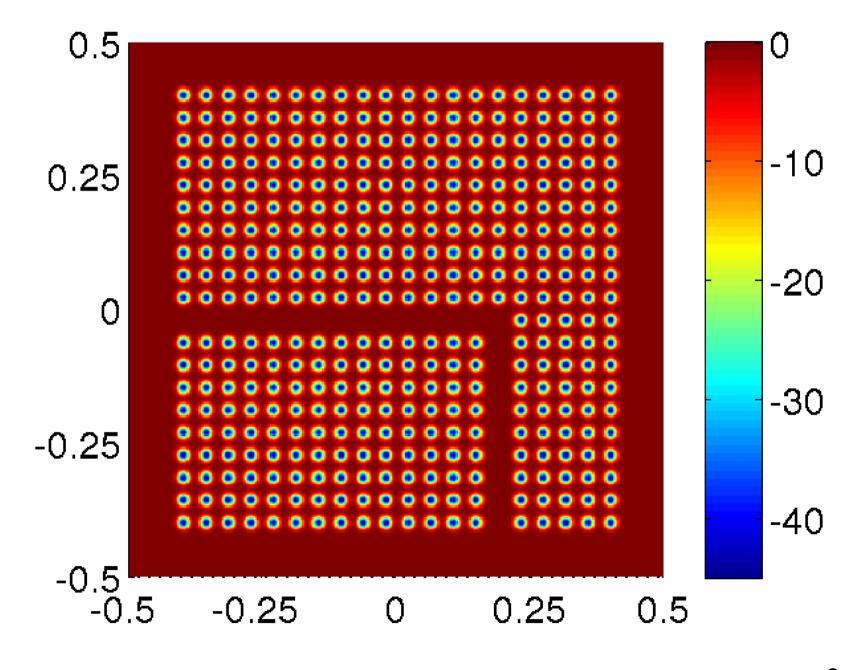

The outgoing field  $u_{\text{out}}$  (resulting from an incoming plane wave  $u_{\text{in}}(x) = \cos(\kappa x_1)$ )

### "FEM-BEM coupling"

$$\left(-\Delta u_{\text{out}}(\boldsymbol{x}) - \kappa^2 \left(1 - b(\boldsymbol{x})\right) u_{\text{out}}(\boldsymbol{x}) = -\kappa^2 b(\boldsymbol{x}) u_{\text{in}}(\boldsymbol{x}) \\
\lim_{|\boldsymbol{x}| \to \infty} \sqrt{|\boldsymbol{x}|} \left(\partial_{|\boldsymbol{x}|} u_{\text{out}}(\boldsymbol{x}) - i\kappa u_{\text{out}}(\boldsymbol{x})\right) = 0$$

The scattering potential b — now a photonic crystal with a wave guide.

$$N = 231\,361$$

$$T_{\rm build} = 7.2 \text{ sec}$$

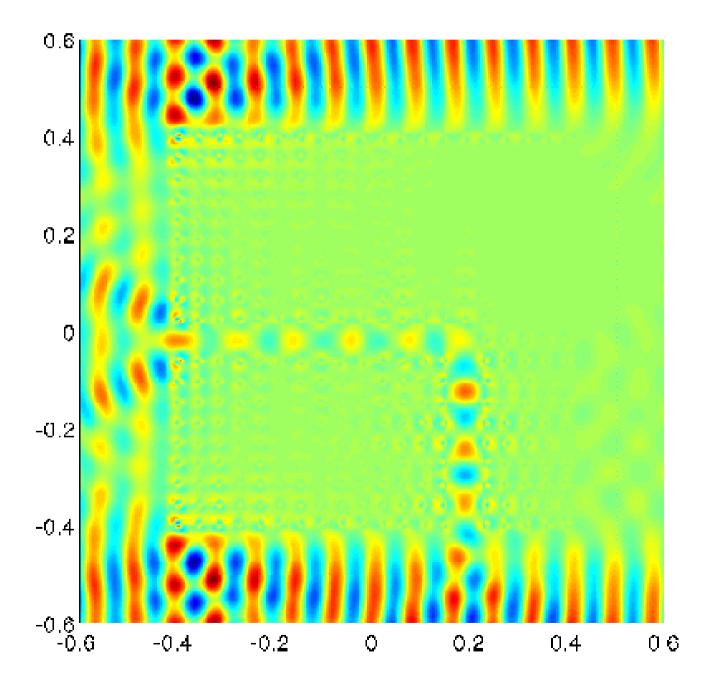

$$T_{
m solve}=0.06~{
m sec}$$

$$N = 231\,361$$
  $T_{\text{build}} = 7.2 \text{ sec}$   $T_{\text{solve}} = 0.06 \text{ sec}$   $E \approx 10^{-6} \text{ (estimated)}$ 

## "FEM-BEM coupling"

$$\begin{cases} -\Delta u_{\text{out}}(\boldsymbol{x}) - \kappa^2 (1 - b(\boldsymbol{x})) u_{\text{out}}(\boldsymbol{x}) = -\kappa^2 b(\boldsymbol{x}) u_{\text{in}}(\boldsymbol{x}) \\ \lim_{|\boldsymbol{x}| \to \infty} \sqrt{|\boldsymbol{x}|} (\partial_{|\boldsymbol{x}|} u_{\text{out}}(\boldsymbol{x}) - i\kappa u_{\text{out}}(\boldsymbol{x})) = 0 \end{cases}$$

The total field  $u = u_{in} + u_{out}$  (resulting from an incoming plane wave  $u_{in}(x) = \cos(\kappa x_1)$ ).

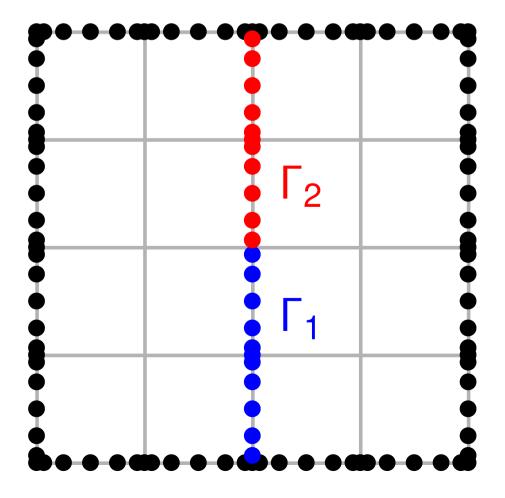

rank deficiencies in HPS

Recall that at the top level, we need to invert a dense matrix that is defined on the nodes of the interface high-lighted in red and blue below. This matrix holds restrictions of the Dirichlet-to-Neumann (DtN) operators for the two blocks. We have claimed that this matrix is rank-structured. *But what are the ranks?*

## **Lippmann-Schwinger**

Consider the free space acoustic scattering problem

(6) 
$$\begin{cases} -\Delta u(\boldsymbol{x}) - \kappa^2 (1 - b(\boldsymbol{x})) u(\boldsymbol{x}) = -\kappa^2 b(\boldsymbol{x}) v(\boldsymbol{x}), & \boldsymbol{x} \in \mathbb{R}^2 \\ \lim_{|\boldsymbol{x}| \to \infty} \sqrt{|\boldsymbol{x}|} (\partial_{|\boldsymbol{x}|} u(\boldsymbol{x}) - i\kappa u(\boldsymbol{x})) = 0, \end{cases}$$

#### where

- b is a smooth scattering potential with compact support, where
- *v* is a given "incoming potential" and where
- *u* is the sought "outgoing potential."

We addressed this problem earlier using a multidomain spectral discretization.

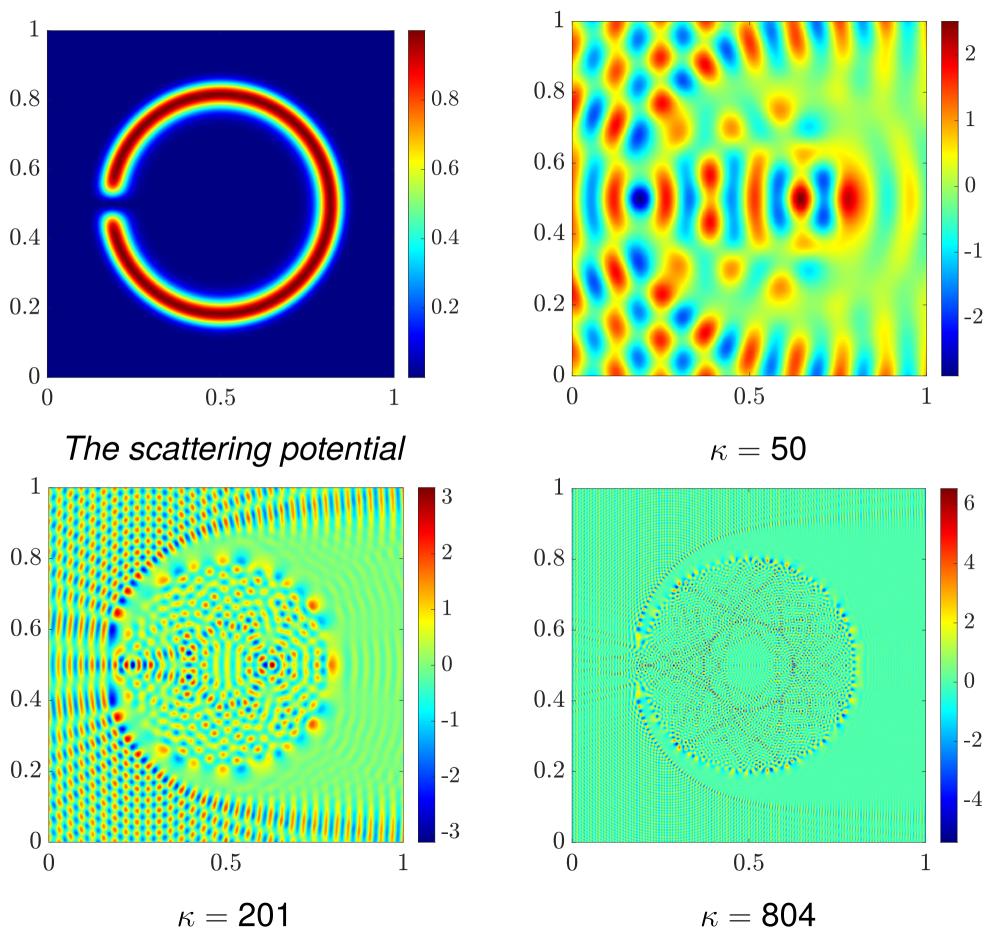

Let us now use an integral equation formulation. It is well known that (6) has an alternative formulation in the *Lippmann-Schwinger integral equation* 

(7) 
$$\sigma(\mathbf{x}) + \kappa^2 b(\mathbf{x}) \int_{\Omega} \phi_{\kappa}(\mathbf{x} - \mathbf{y}) \sigma(\mathbf{y}) d\mathbf{y} = -\kappa^2 b(\mathbf{x}) v(\mathbf{x}), \qquad \mathbf{x} \in \Omega,$$

where  $\phi_{\kappa}$  is the free space fundamental solution of the Helmholtz equation.

We discretize (7) using the trapezoidal rule on a uniform grid, with Duan-Rokhlin quadrature corrections of order 10.

## **Lippmann-Schwinger**

Lippmann-Schwinger

Fixed 10 points per wavelength.

Direct solver is run at accuracy  $10^{-3}$  and used as a preconditioner.

Weak admissibility is used.

N	$\kappa$	T <sub>build</sub>	$T_{inv}$	T <sub>gmres</sub>	mem	iter	res

The largest experiment is over  $500\lambda$  in diameter: Less than 3h total run time.

Hardware: Workstation with dual Intel Xeon Gold 6254 (18 cores at 3.1GHz base frequency).

Joint with Abi Gopal, arxiv #2007.12718

## rough surface scattering

Consider acoustic scattering from an infinite half-plane with  $8 \times 8$  bumps:

Each bump is  $0.5\lambda$  tall and  $2\lambda$  wide. Total domain is  $44\lambda \times 44\lambda$ .

The problem is formulated as a BIE, and is discretized using a "Zeta-corrected" quadrature rule. A direct solver with weak admissibility and  $O(N^{1.5})$  scaling is used.

26M points total,  $T_{\text{build}} = 1200s$ ,  $T_{\text{solve}} = 184s$ 

About three digits of accuracy in the computed solution. (Tentative!)

Work in progress - with Abi Gopal and Bowei Wu.

# **Key Ideas:**

The solution operator of a linear elliptic PDE is "friendly."

- Smoothing.
- Stable.

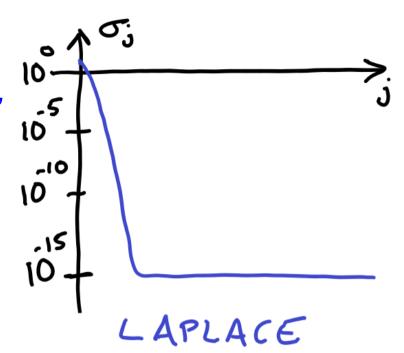

## **Key Ideas:**

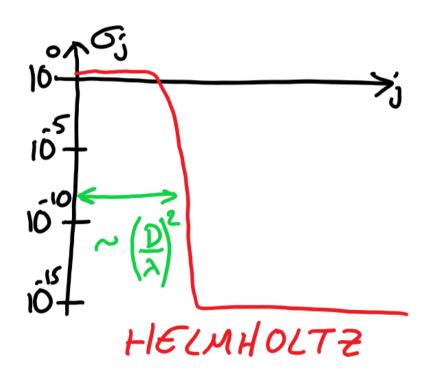

The solution operator of a linear elliptic PDE is "friendly."

- Smoothing.
- Stable.

### Long range interactions are low rank.

- Cf. St Venant principle, multipole expansions, etc.
- Smoothness is *not* necessary.
- Numerical compression is essential.
- Wave problems with small  $\lambda$  remain challenging.

## **Key Ideas:**

The solution operator of a linear elliptic PDE is "friendly."

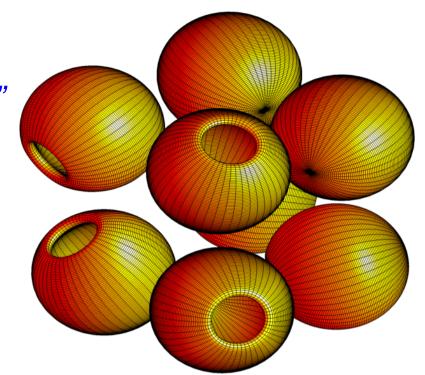

- Smoothing.
- Stable.

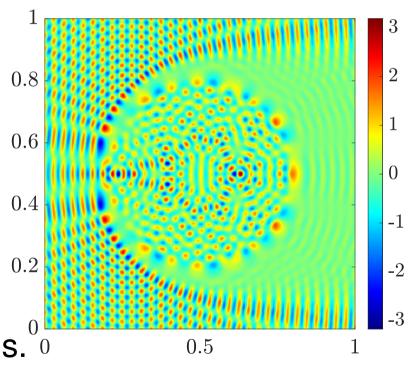

### Long range interactions are low rank.

- Cf. St Venant principle, multipole expansions, etc.
- Smoothness is *not* necessary.
- Numerical compression is essential.
- Wave problems with small  $\lambda$  remain challenging.

### High-order discretizations + FDS.

- Maximize the work done by each DOF to save memory.
- Perfect for ill-conditioned problems with oscillatory solutions.
- Requires care in choosing discretization scheme.

New randomized methods for matrix algebra → acceleration & simplification.

#### Where we are now:

- We have developed direct solvers with O(N) complexity for elliptic PDEs with non-oscillatory (or "mildly oscillatory") solutions for most standard environments:
  - Sparse matrices from FEM/FD/composite spectral/... in both 2D and 3D.
  - Boundary integral equations in 2D and 3D. (Work in progress ...)
- Advantages of direct solvers:
  - Often instantaneous solves once a solution operator has been built.
  - Can eliminate problems with slow convergence of iterative solvers.
  - Communication efficient.
- Disadvantages of direct solvers:
  - Memory hogs. (But distributed memory is OK.)
  - The build stage is still slow for many 3D problems. (I am optimistic that we will fix this!)

### Where to go next:

New powerful tool available → lots of opportunities!

- Explore happy couplings:
  - Direct solver + high order discretization.

(Helps with memory. Wave problems.)

• Direct solver + integral equation formulations.

(Need dense matrices anyway.)

• Direct solver + parallelization.

(Root of tree is cheap!)

• Direct solver + numerical coarse graining.

(Another talk...)

• Parabolic and hyperbolic problems. Parallel-in-time methods?
